## DEDICATION

This thesis is dedicated to my family who always raised me with the strong values of persistence and dedication to always perform to the best of my efforts. To my sister and my brother-in-law who provided support and guidance throughout this crucial time, which will define my future.

## ACKNOWLEDGMENTS

I would like to express my sincere gratitude to my major professor, Dr. Irtishad Ahmad, P.E., for his guidance and advice during my graduate study at FIU.

I am grateful to Mr. Mehdi Ashraf, P.E., for inspiring me about the research topic and encouraging me to do my best in perusing this research. I am indebted to Professor Luis Prieto-Portar, Ph.D., P.E. and Professor Ton-Lo Wang, Ph.D., P.E., members of my thesis committee, for their continuous support and advice during the research study.

Finally, I would like to express my appreciation to the staff of the Department of Civil and Environmental Engineering for their help and kindness

ABSTRACT OF THE THESIS

ANALYSIS AND DESIGN OF TALL CONCRETE BUILDINGS: AN  
INVESTIGATION REGARDING THE USE OF CRACKED VERSUS UN-CRACKED  
MOMENT OF INERTIA

by

Anas Bataineh

A debate is currently prevalent among the structural engineers regarding the use of cracked versus un-cracked moment of inertia of the structural elements in analyzing and designing tall concrete buildings. (The basic definition of a tall building, according to the *Journal of Structural Design of Tall Buildings* Vol. 13, No. 5, 2004 is a structure that is equal to or greater than 160 feet in height, or 6 stories or greater.) The controversy is the result of differing interpretations of certain ACI (American Concrete Institute) code provisions. The issue is whether designers should use cracked moment of inertia in order to estimate lateral deflection and whether the computed lateral deflection should be used to carry out subsequent second-order analysis (analysis considering the effect of first-order lateral deflections on bending moment and shear stresses). On one hand, bending moments and shear forces estimated based on un-cracked moment of inertia of the sections may result in conservative designs by overestimating moments and shears. On the other hand, lateral deflections may be underestimated due to the same analyses resulting in unsafe designs.

## LIST OS SYMBOLS

$\Phi$ : Strength reduction factor.

$\Delta_o$ : Lateral displacement due to ultimate lateral forces.

$\delta_{ns}$ : ACI code nonsway moment magnification factor.

$\delta_s$ : ACI code sway moment magnification factor.

$D_m$ : percentile difference between the first and second analyses sway moments.

$D_{ns2}$ : percentile difference between the first and second analyses gravity moments.

$h$ : the dimension of the column square cross-section.

$I_{cre}$ : Effective moment of inertia of the column cracked section.

$I_{ge}$ : Effective moment of inertia of the column gross section.

$k$ : Effective length factor.

$M_u$ : Ultimate Bending Moment.

$P_c$ : Critical buckling load.

$P_u$ : Ultimate axial load.

$Q$ : Stability index.

$V_u$ : Ultimate shear force.

## CHAPTER 1

### INTRODUCTION

#### 1.1 PROBLEM STATEMENT:

A debate is currently prevalent among the structural engineers regarding the use of cracked versus un-cracked moment of inertia of the structural elements in analyzing and designing tall concrete buildings. The controversy is the result of differing interpretations of certain ACI (American Concrete Institute) code provisions. The issue is whether designers should use cracked moment of inertia in order to estimate lateral deflection and whether the computed lateral deflection should be used to carry out subsequent second-order analysis (analysis considering the effect of first-order lateral deflections on bending moment and shear stresses). On one hand, bending moments and shear forces estimated, based on un-cracked moment of inertia, may result in conservative designs by overestimating moments and shears. On the other hand, lateral deflections may be underestimated due to the same analyses resulting in unsafe designs. The ACI code provisions leave room for widely differing predictions and do not provide clear guidelines.

## 1.2 SCOPE:

The scope of this investigation is limited to determining theoretically the behavior of columns in tall concrete buildings under lateral forces. A commercially available computer software package, employing the finite element method (FEM) is used to carry out the analytical investigation. Four buildings with different story heights are modeled, each has the same structural configuration (one bay by one bay), material properties and number of stories (30 stories).

The structural configuration of the buildings is chosen based on the following:

- 1) Each one of the buildings satisfies the definition of the tall building.
- 2) The story height of each building is different; different lateral deflections and moments will be induced causing different *P-Delta* (second order) effects.
- 3) All the structural elements in the buildings are designed according to ACI Code provisions.

Three types of analyses are performed for each building, un-cracked first order, un-cracked second order (*P-Delta*) and cracked second order (*P-Delta*). The results are used to investigate the ACI Code moment magnification factors and the behavior of columns in concrete buildings.

### 1.3 OBJECTIVES:

- 1) To investigate the applicability of ACI Code moment magnifier method in terms of slenderness ratio ( $kL_u/r$ ) ranges for braced and sway columns (unbraced).
- 2) To investigate behavior of tall concrete buildings analytically under lateral force effects with different story heights based on cracked and un-cracked moment of inertia of the structural members sections.
- 3) To develop an improved procedure for analysis taking realistic behavior of tall concrete buildings under ultimate loads (gravity & lateral) into account.
- 4) To develop graphical design aids for assisting structural engineers.

## CHAPTER 2

### BACKGROUND

#### **2.1 ACI METHOD: SUMMARY**

Tall or high-rise buildings are typically statically indeterminate structures. That means, bending moments and shear forces induced in the structural elements (mainly beams and columns) are dependent on deflections (work done by the external loads) in these members, and these deflections vary according to the stiffness (moment of inertia) of structural elements. The structural elements are designed to carry the ultimate applied loads; these loads will force the structure to deform in a way to reach the stable condition (work done by external loads equals to the work done by internal loads). Accordingly, the flexural rigidity of the structural elements will be decreased due to cracking of the sections; further deformations will be induced because of the increase in flexibility of that structure.

First, the study was conducted by going through ACI code provisions to investigate the methodology suggested in ACI research to come up with the moment magnifier method and the underlying assumptions that led to this methodology.

Section 10 in ACI code 2002 was the main reference to this research investigation, all of the variables controlling the analysis and design processes were studied in depth in order to understand the rationale used by ACI.

In *ACI R10.13.3* it is mentioned that the analysis described in moment magnifier method deals only with plane frames subjected to loads causing deflections in that plane. If torsional displacements are significant, a three-dimensional second-order analysis is suggested. In this research only symmetrical buildings in geometry and loading are

considered. Thus no torsional displacements are significant in any building used in this research.

In *ACI R10.13.4.1* it is mentioned that a second-order analysis is a frame analysis that includes the internal force effects resulting from deflections. When a second-order elastic analysis is used to compute  $\delta_s M_s$ , magnified moments due to lateral loads, and the deflections should be representative of the stage immediately prior to the ultimate load. For this reason the reduced  $E_c I_g$  values given in *10.11.1* should be used in the second-order analysis.

(b) Moments of inertia	
Beams.....	$0.35I_g$
Columns.....	$0.70I_g$
Walls—Uncracked.....	$0.70I_g$
—Cracked .....	$0.35I_g$
Flat plates and flat slabs .....	$0.25I_g$

ACI uses a factor called  $\beta_d$  to account for cracking in structural members due to creep and shrinkage. The term  $\beta_d$  is defined differently for non-sway and sway.

$\beta_d$  = (a) for nonsway frames,  $\beta_d$  is the ratio of the maximum factored axial sustained load to the maximum factored axial load associated with the same load combination;  
(b) for sway frames, except as required in (c) of this definition,  $\beta_d$  is the ratio of the maximum factored sustained shear within a story to the maximum factored shear in that story;  
(c) for stability checks of sway frames carried out in accordance with *10.13.6*,  $\beta_d$  is the ratio of the maximum factored sustained axial load to the maximum factored axial load

In this research no shear walls were used, shear walls takes all of the lateral loads applied to the concrete building and the main function of the other structural members will be to carry the gravity loads only. So, the stability index ( $Q$ ) was used to distinguish between a braced story and a sway story, *ACI 10.11.4.2* was used:

**10.11.4.2** — It also shall be permitted to assume a story within a structure is nonsway if:

$$Q = \frac{\Sigma P_u A_o}{V_u \ell_o} \quad (10-6)$$

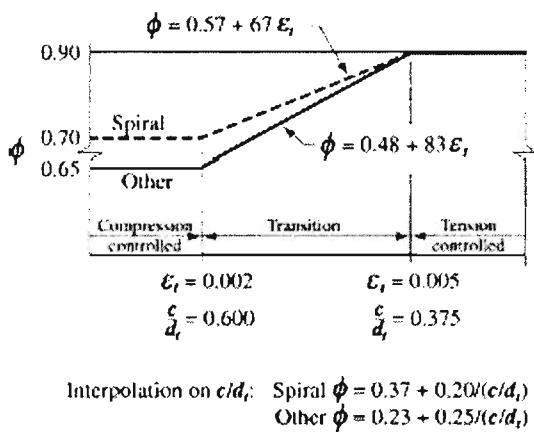

is less than or equal to 0.05, where  $\Sigma P_u$  and  $V_u$  are the total vertical load and the story shear, respectively, in the story in question and  $A_o$  is the first-order relative deflection between the top and bottom of that story due to  $V_u$ .

In *ACI R10.11.4* it is mentioned that the moment magnifier design method requires the designer to distinguish between non-sway frames, (designed according to 10.12) and sway frames (designed according to 10.13). Frequently this can be done by inspection by comparing the total lateral stiffness of the columns in a story to that of the bracing elements. A compression member may be assumed non-sway by inspection if it is located in a story in which the bracing elements (shear walls, shear trusses, or other types of lateral bracing) have such substantial lateral stiffness to resist the lateral deflections of the story that any resulting lateral deflection is not large enough to affect the column strength substantially. If not readily apparent by inspection, 10.11.4.1 and 10.11.4.2 give two possible ways of doing this. In 10.11.4.1, a story in a frame is said to be non-sway if the increase in the lateral load moments resulting from *P-Delta* effects does not exceed 5 percent of the first-order moments. 10.28 Section 10.11.4.2 gives an alternative method of determining this based on the stability index for a story  $Q$ . In computing  $Q$ ,  $\Sigma P_u$  should correspond to the lateral loading case for which  $\Sigma P_u$  is greatest. A frame may contain both non-sway and sway stories. This test would not be suitable if  $V_u$  is zero.

ACI also specifies another limit, in addition to the above, for the use of the moment magnifier method. Slenderness Ration ( $kL_u/r$ ) must be less than 100, otherwise the moment magnifier method is not applicable any more, and all of the columns in all of the three buildings used in this research satisfy that limit.

The effective length factor ( $k$ ) was calculated according to *ACI 10.12*, taking into account the connection condition for each column and whether the story investigated is Braced or not (sway).

The strength reduction factor ( $\phi$ ) was calculated for each column in accordance with *ACI 9.3.2*:

The ACI Code specifies a limit for the compression member steel reinforcement Ratio, with a maximum of 8% going down to a minimum of 1% of the gross cross-sectional area, in this research a steel reinforcement ration of 1.5% was used.

## **10.9 — Limits for reinforcement of compression members**

**10.9.1 — Area of longitudinal reinforcement for non-composite compression members shall be not less than 0.01 nor more than 0.08 times gross area  $A_g$  of section.**

### **2.2 DESCRIPTION OF ACI CODE PROCEDURE:**

In this section, the ACI procedure for designing compression members is given:

1. Specify which materials properties will be used in the analysis and design of the structural member,  $f'_c$  (concrete compressive strength),  $\gamma$  (unit weight of concrete),  $f_y$  (grade of reinforcing steel).
2. Assume preliminary section dimensions.
3. From the analysis results, using the axial loads, moments and shears for each load case (dead, live, wind... etc), calculate the ultimate load combinations. And find which combination is the most critical for design.
4. Determine whether the story is sway or non-sway using the ACI limits for the stability index ( $Q$ ).
5. calculate the effective length factor using the equations/charts provided by ACI, then calculate the slenderness ratio and find out if the member is slender or not. Make sure ( $kL_u/r$  is less than 100).
6. calculate the magnifier factors:
  - a) If the member is non-sway and short: no magnifications of moments are required.
  - b) If the member is non-sway and Slender: gravity load combination should be magnified by  $\delta_{ns}$ .

- c) If the member is sway and short: no magnifications of moments are required.
- d) If the member is sway and Slender: gravity load combination must be magnified by  $\delta_{ns}$  if  $[L_u/r > 35/(P_u/f'_c A_g)^{0.5}]$  and the sway moments must be magnified by  $\delta_s$ .
- e) If the member is sway and Slender: if  $[L_u/r < 35/(P_u/f'_c A_g)^{0.5}]$  no magnification is required for gravity load combination and the sway moments must be magnified by  $\delta_s$ .

7. Calculate the Design moment, magnified ultimate moment, and the ultimate axial load.
8. Calculate the actual eccentricity and the minimum eccentricity specified by ACI code and take which ever is the greater.
9. Calculate the nominal axial load and moment by dividing the forces from step (7) with the strength reduction factor.
10. Using the interaction diagrams or equations solving find out the required steel ratio.
11. Check if the section is adequate, if not go back to step 2 and increase the section dimensions.

## 2.3 COMPUTER MODELING:

### 2.3.1 DESCRIPTION OF BUILDINGS:

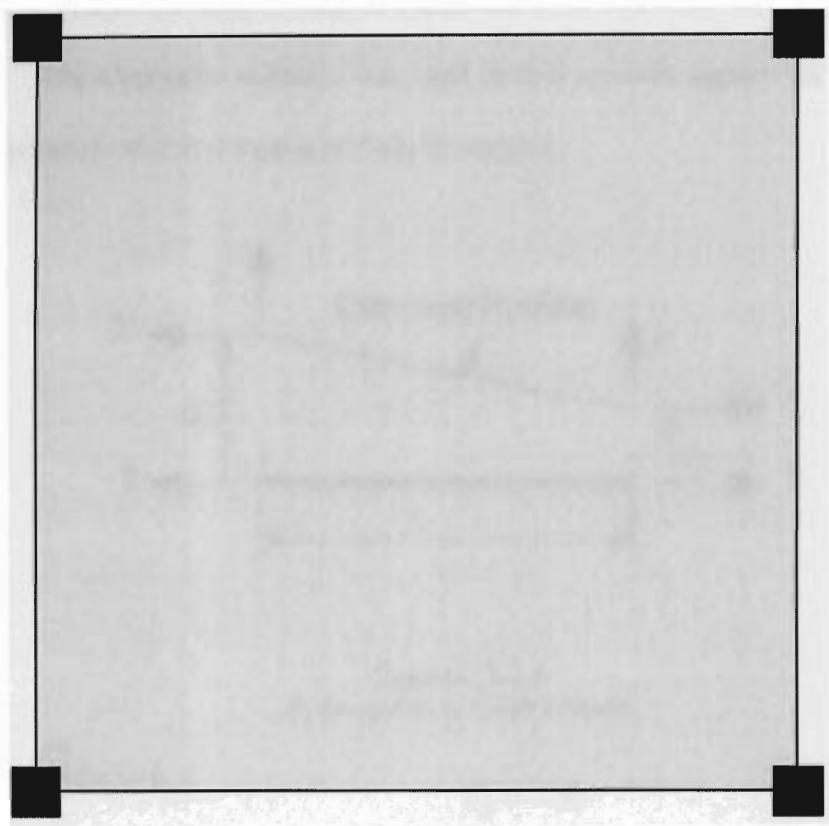

The typical building used for analysis in this research is described below:

- 1) Thirty Story building.
- 2) Four building with four different story heights: 18 ft, 24 ft, 30 ft and 36 ft.

- 3) One bay by one bay of 24 ft span.
- 4) Each story consists of 4 corner columns, 4 beams and a concrete slab connecting them.
- 5) The applied loads on the concrete slab are 20 psf dead and 80 psf live load.
- 6) The applied lateral load on the columns is the wind load with a speed of 150 MPH.

Figure 2.3.1.1a  
Elevation view of the typical building used in this research

**Figure 2.3.1.1b**  
Plan view of the typical building used in this research

### 2.3.2 DESCRIPTION OF THE COMPUTER ANALYSIS PROGRAM:

The Computer software was used in this research applies the concept of the geometric stiffness matrix in P-Delta analysis.

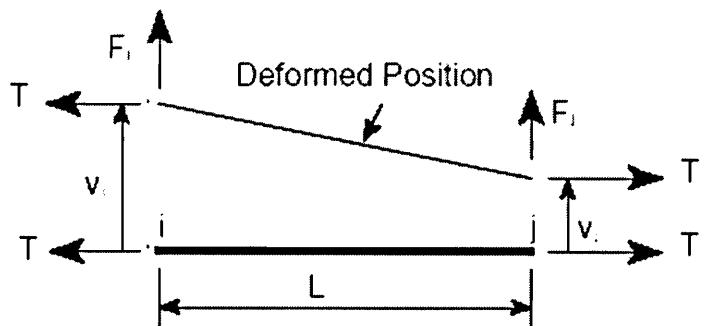

Figure 2.3.2.1  
Forces acting on a cable element

$$F_i = \frac{T}{L}(v_i - v_j) \quad F_j = -F_i$$

$$\begin{bmatrix} F_i \\ F_j \end{bmatrix} = \frac{T}{L} \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} v_i \\ v_j \end{bmatrix} \quad \text{or symbolically, } \mathbf{F}_g = \mathbf{k}_g \mathbf{v}$$

The Geometric Stiffness matrix ( $\mathbf{k}_G$ ):

$$\begin{bmatrix} F_i \\ M_i \\ F_j \\ M_j \end{bmatrix} = \frac{T}{30L} \begin{bmatrix} 36 & 3L & -36 & 3L \\ 3L & 4L^2 & -3L & -L^2 \\ -36 & -3L & 36 & -3L \\ 3L & -L^2 & -3L & 4L^2 \end{bmatrix} \begin{bmatrix} v_i \\ \phi_i \\ v_j \\ \phi_j \end{bmatrix} \quad \text{or, } \mathbf{F}_G = \mathbf{k}_G \mathbf{v}$$

The Elastic Stiffness without Shear Deformations:

$$\begin{bmatrix} F_i \\ M_i \\ F_j \\ M_j \end{bmatrix} = \frac{EI}{L^3} \begin{bmatrix} 12 & 6L & -12 & 6L \\ 6L & 4L^2 & -6L & -2L^2 \\ -12 & -6L & 12 & -6L \\ -6L & -2L^2 & -6L & 4L^2 \end{bmatrix} \begin{bmatrix} v_i \\ \phi_i \\ v_j \\ \phi_j \end{bmatrix} \quad \text{or. } \mathbf{F}_E = \mathbf{k}_E \mathbf{v}$$

The Total stresses acting on a member are:

$$\mathbf{F}_T = \mathbf{F}_E + \mathbf{F}_G = [\mathbf{k}_E + \mathbf{k}_G] \mathbf{v} = \mathbf{k}_T \mathbf{v}$$

In building analysis the lateral movement of a story mass to a deformed position generates second-order overturning moments. This second-order behavior has been termed the *P-Delta* effect since the additional overturning moments on the building are equal to the sum of story weights “*P*” times the lateral displacements “*Delta*”.

Many techniques have been proposed for evaluating this second-order behavior. Some methods consider the problem as one of geometric non-linearity and propose iterative solution techniques that can be numerically inefficient. Also, these iterative methods are not appropriate for dynamic analysis where the *P-Delta* effect causes lengthening of the periods of vibration. However, the simple approach used in their derivation should add physical insight to the understanding of *P-Delta* behavior in buildings.

The procedure involving *P-Delta* analysis can be summarized as follows:

1. Choose geometrical sections of the frame and its columns and their stiffness (*EI*) by approximate procedure.

2. Calculate the drifts (later deflections  $\Delta_i$ ) and the corresponding ultimate loads ( $P_u$ ) at joints  $i=1, 2\dots n$ . (as in the figure).

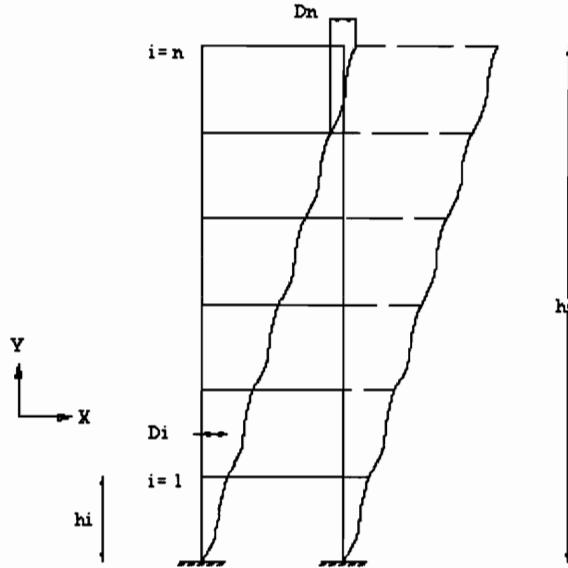

Figure 2.3.2.2  
Deformed shape of the typical building used in this research

3. Find the equivalent horizontal forces ( $H_i = P_i \Delta_i / h_i$ )
4. Add the values obtained in step 3 to the actual lateral loads acting on the frame.
5. Perform a frame analysis using approximate computer program (or hand analysis).
6. The iterative computer program, using the stiffnesses ( $EI$ ), chosen for the input data gives  $\Delta_i$  results that have to be compared with the previous analysis results.

7. If all  $\Delta_i$  are less than or equal the ones obtained from the preceding analysis, accept the analysis. If not run more cycles and modify the stiffnesses.

The *P-Delta* problem can be linearized and the solution to the problem can be obtained directly and exactly, without iteration, in building type structures where the weight of the structure is constant during lateral motions and the overall structural displacements can be assumed to be small compared to the structural dimensions.

The method does not require iteration since the total axial force at a story level is equal to the weight of the building above that level and does not change during the application of lateral loads. Therefore, the sum of the column of geometric stiffness terms associated with the lateral loads cancels and only the axial forces due to the weight of the structure need to be included in the evaluation of the geometric stiffness terms for the entire building.

## CHAPTER 3

### METHODOLOGY

#### 3.1 DESCRIPTION OF ANALYSIS AND DESIGN PROCEDURE:

In this section the analysis and design procedure of a typical building is described in detail, including the assumptions made to get the results obtained.

After choosing the structural configuration of the typical building, material properties and dimensions, the building was modeled using the commercially available FEM software. Assuming preliminary sections of the structural members the first order un-cracked analysis was performed. Using the axial loads, moments and shears obtained from that analysis the structural members were designed to resist the ultimate loads applied. Then, the new sections were input again to the computer model and the first order un-cracked analysis was performed and a new set of member forces was obtained. The structural members were designed again to carry the new forces of the second analysis, if the input sections were different from the output (designed) sections, the analysis operation would be repeated until input sections were within 10% difference from output sections.

After finishing the design for the first order un-cracked analysis and making sure that all of the structural members would carry the applied loads, a *P-Delta* un-cracked (second order) analysis was performed to account for the additional moments induced because of the building lateral drifts. Once that is done, another check would be performed for the capacity of the building's structural members; if any member fails to carry its assigned loads the section of that member must be redesigned.

Using the design results obtained (sections dimensions, depth of the compression block of the section and the longitudinal area of the reinforcing steel), the effective cracked and the effective gross moments of inertia of each section is calculated and a ratio of cracked to un-cracked moments of inertia were calculated. These ratios would be entered into the computer model to modify each member's stiffness. A *P-Delta* (second order) analysis of the modified building is performed and a new set of results would be obtained (the structural members would pass the strength capacity check but the lateral drifts for each story would be increased).

The section of each structural member would be modified in a way to balance the lateral drifts of the first order un-cracked analysis with the second order (*P-Delta*) cracked analysis. That was done by increasing the sections as a function of the increase in the lateral drifts of each story.

Sets of graphs comparing the results obtained were drawn for each one of the four buildings and conclusions were made regarding the behavior of the buildings described in these graphs.

### 3.2 DESCRIPTION OF THE MATHCAD SHEET USED FOR DESIGN:

A *MathCAD* sheet was created to facilitate the process of design and comparing the results between the three types of analysis were performed for each building.

Here is a summary of the input and output obtained from the *MathCAD* sheet:

#### Input:

- 1) First order and second order axial loads, moments, shears and lateral deflections of each story (dead, live and wind) were exported from the analysis software to Microsoft excel then as an input file to *MathCAD*.
- 2) The *MathCAD* sheet will calculate the ultimate loads applied to the structural member and the moment's modification factors to prepare the process of design.
- 3) The reinforcing steel ratio can be changed in the sheet; a value of 1.5% was used throughout in this research.

#### Output:

- 1) Section dimensions.
- 2) Unsupported length of column.
- 3) Area of longitudinal reinforcing steel.
- 4) Effective length factor ( $k$ ).
- 5) Slenderness Ratio ( $kL_u/r$ ).
- 6) Whether the story is sway or non-sway (braced).
- 7) Whether the columns of each story are slender or short.
- 8) Stability Index ( $Q$ ).
- 9) Non-sway moment magnification factor.
- 10) Sway moment magnification factor.

- 11) Capacity ratios of the section.
- 12) Compression block dimension ( $c$ ).
- 13) Strength Reduction Factor ( $\phi$ ).
- 14) Difference in first order and second order ( $P$ - $\Delta$ ) non-sway moments.
- 15) Difference in first order and second order ( $P$ - $\Delta$ ) sway moments.
- 16) Effective cracked moment of inertia ( $I_{cre}$ ).
- 17) Effective gross moment of inertia ( $I_{ge}$ ).
- 18) The ratio of cracked to un-cracked moments of inertia.

The *MathCAD* sheet applies the design provisions of ACI Code for compression members; here is the process of design using the *MathCAD* sheet:

- 1) Importing the output file from the Computer's software analysis results.
- 2) Calculating the ultimate loads applied to the structural member.
- 3) Calculating the stability index of the story.
- 4) Determining if the story is braced or sways.
- 5) Calculating the creep factor for the situation applied.
- 6) Calculating the relative stiffnesses of the column-beam connection.
- 7) Calculating the effective length factor.
- 8) Calculating the slenderness ratio.
- 9) Determining if the structural member is short or slender.
- 10) Calculating the critical buckling load.
- 11) Calculating the non-sway moment magnification factor.
- 12) Calculating the sway moment magnification factor.
- 13) Calculating the design ultimate axial load, moment and eccentricity.

- 14) Performing the design process to carry the ultimate loads.
- 15) Calculating capacity ratios, stresses in compression and tension steels and the strength reduction factor.
- 16) Calculating the differences in first order and second order analysis results.
- 17) Calculating the effective cracked and gross moments of inertia.
- 18) Calculating the ratio of cracked to un-cracked moments of inertia.
- 19) Exporting the results to an excel output file to perform the output analysis in excel.

## CHAPTER 4

### RESULTS

#### 4.1 OVERVIEW:

After finishing the analysis and design processes and calculating the output parameters of interest in each building, a set of three graphs was drawn to compare the research results with the ACI code recommendations.

The first graph compares the sway moment modification factor with the real difference in the un-cracked first order and second order analyses sway moments with respect to the varying slenderness ratio for each story of the building.

The second graph compares the non-sway modification factor with the real difference in the un-cracked first order and second order analyses non-sway moments with respect to the varying slenderness ratio for each story of the building.

The third graph gives an indication of the increase in the cross-sectional dimensions from the first order un-cracked analysis to the second order (P-Delta) cracked analysis to get the same lateral deflections with respect to each story.

## 4.2 DESCRIPTION OF FIGURES:

For each building, a set of three graphs is shown:

1) Sway stories:

A comparison graph represents the ACI sway magnification factors

$$\left( \delta_s = \frac{1}{1-Q} \text{ or } \frac{1}{1 - \frac{\sum P_u}{0.75 \sum P_c}} \right) \text{ versus the percentage difference from first order}$$

sway moment to second order sway moment ( $D_m$ ).

2) Braced stories:

A comparison graph represents the ACI nonsway magnification factors

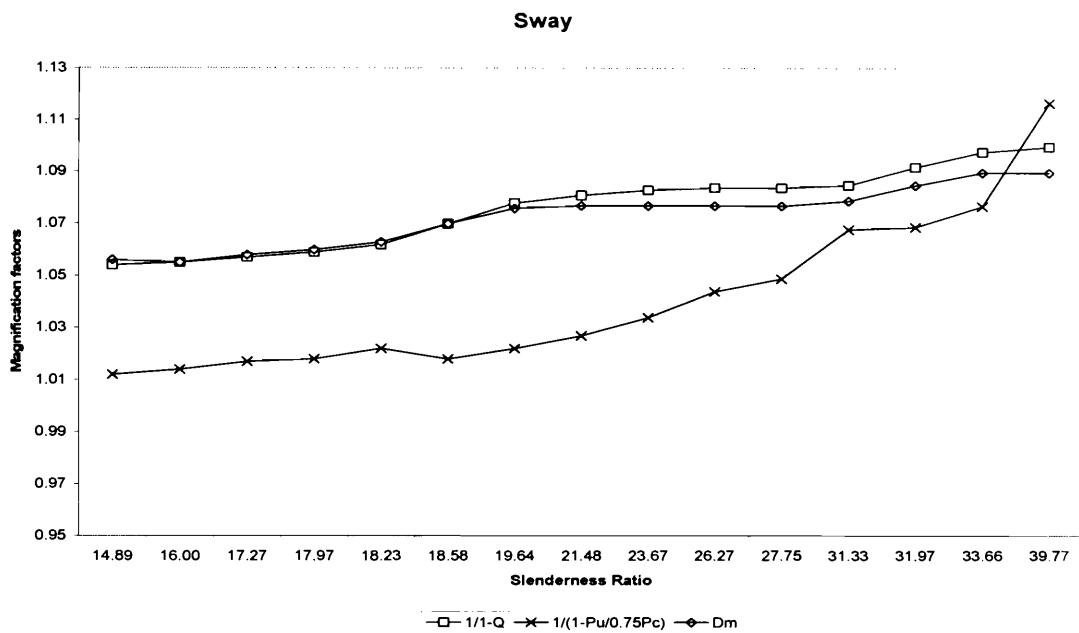

$$\left( \delta_{ns} = \frac{1}{1 - \frac{P_u}{0.75 P_c}} \right) \text{ versus the percentage difference from first order gravity}$$

moment to second order gravity moment ( $D_{ns2}$ ).

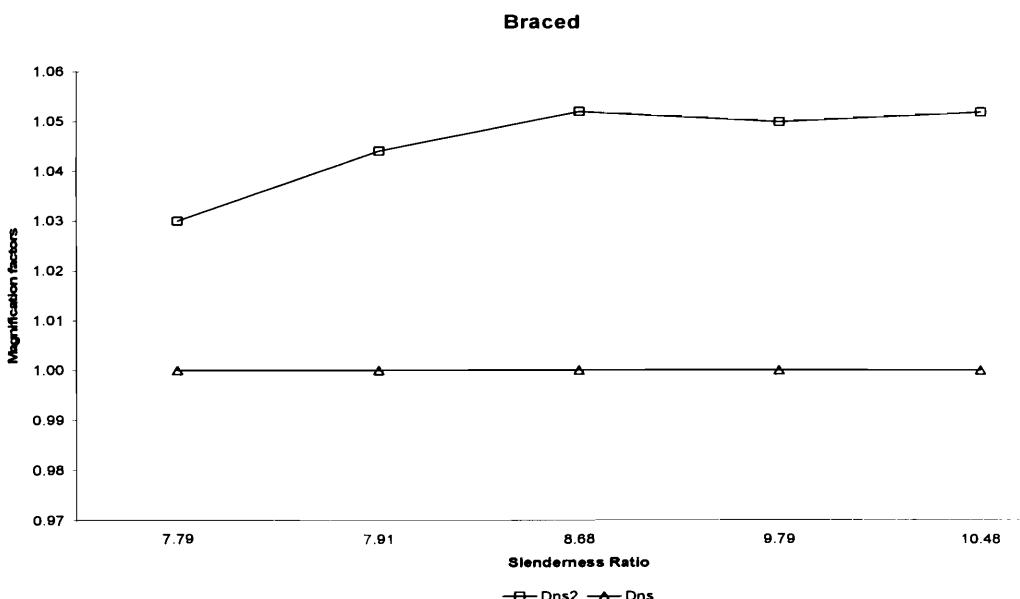

3) The percentage increase in the square column dimension ( $h$ ) to equate the first order uncracked lateral deflections to the second order cracked lateral deflections versus story.

### 4.3 ANALYSIS RESULTS:

- 1) The 18 ft story height building:

**Figure 4.3.1**  
ACI sway magnifier factors vs. the ratio of second order to first order moments

**Figure 4.3.2**  
ACI non-sway magnifier factors vs. the ratio of second order to first order moments

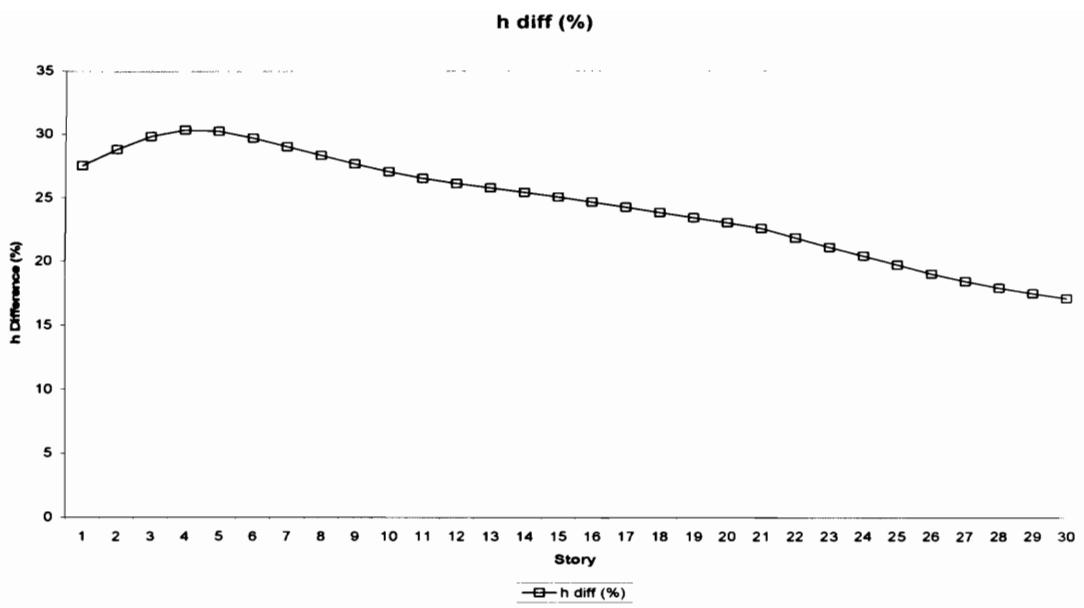

Figure 4.3.3

Percentile increase in the square cross- section dimension of a column to equate the un-cracked first order to the cracked second order lateral deflections with respect to story

2) The 24 ft story height building:

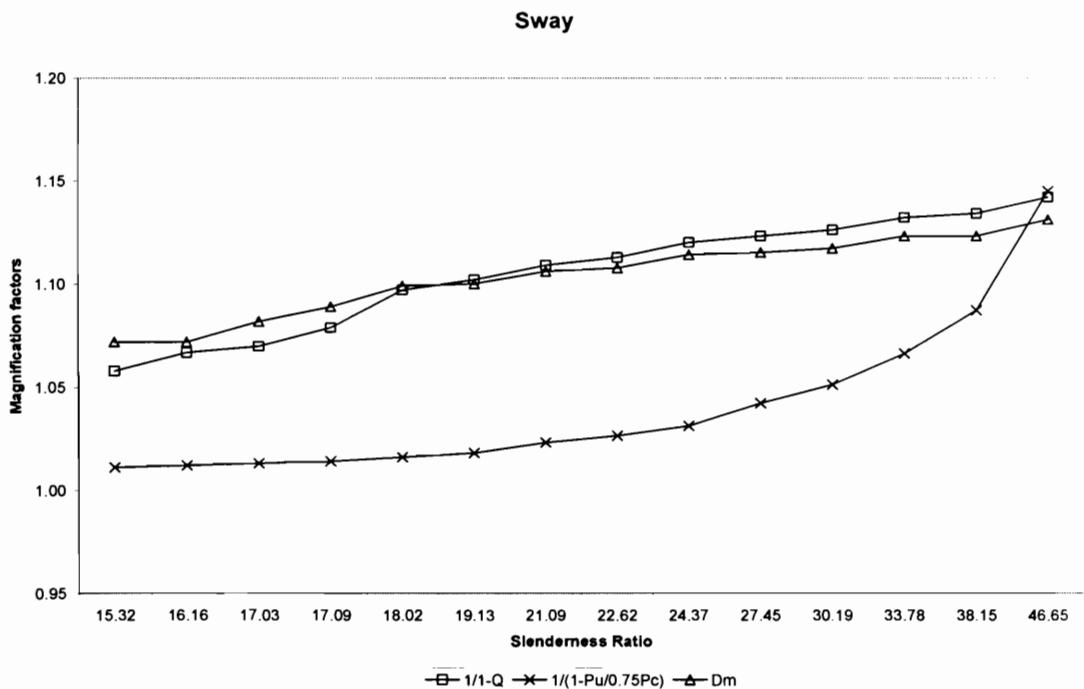

Figure 4.3.4

ACI sway magnifier factors vs. the ratio of second order to first order moments

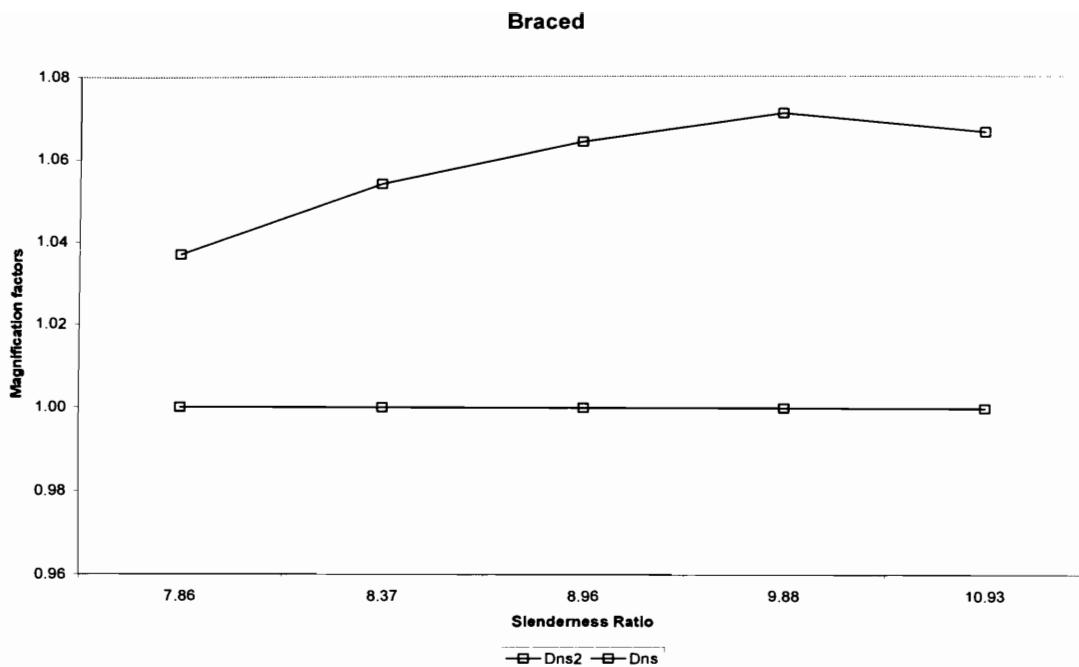

Figure 4.3.5  
ACI non-sway magnifier factors vs. the ratio of second order to first order moments

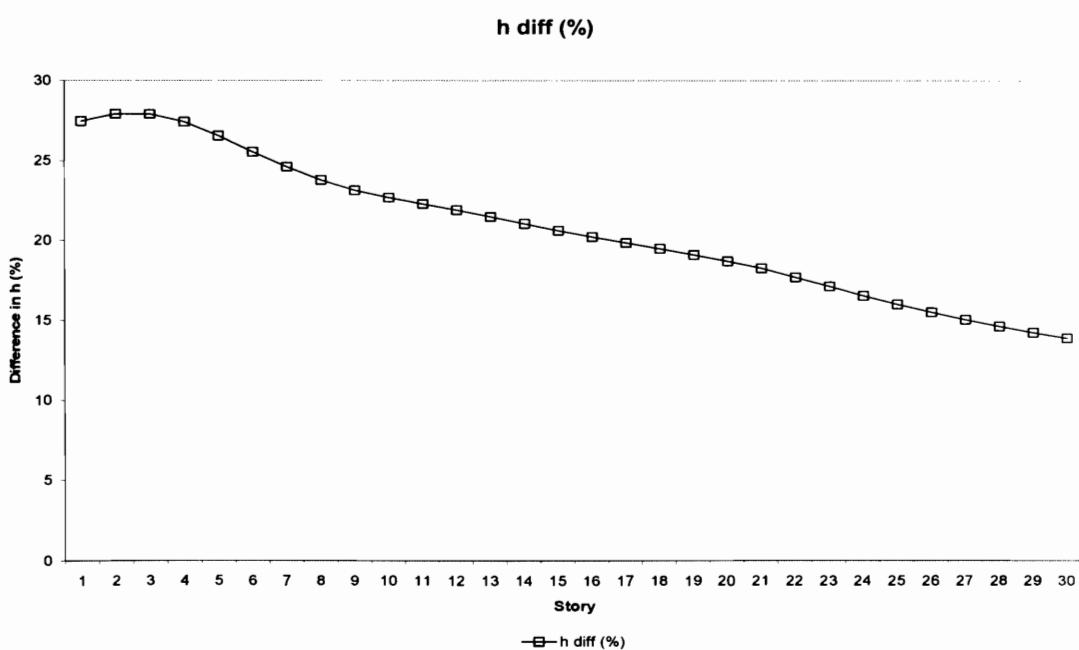

Figure 4.3.6  
Percentile increase in the square cross- section dimension of a column to equate the un-cracked first order to the cracked second order lateral deflections with respect to story

3) The 30 ft story height building:

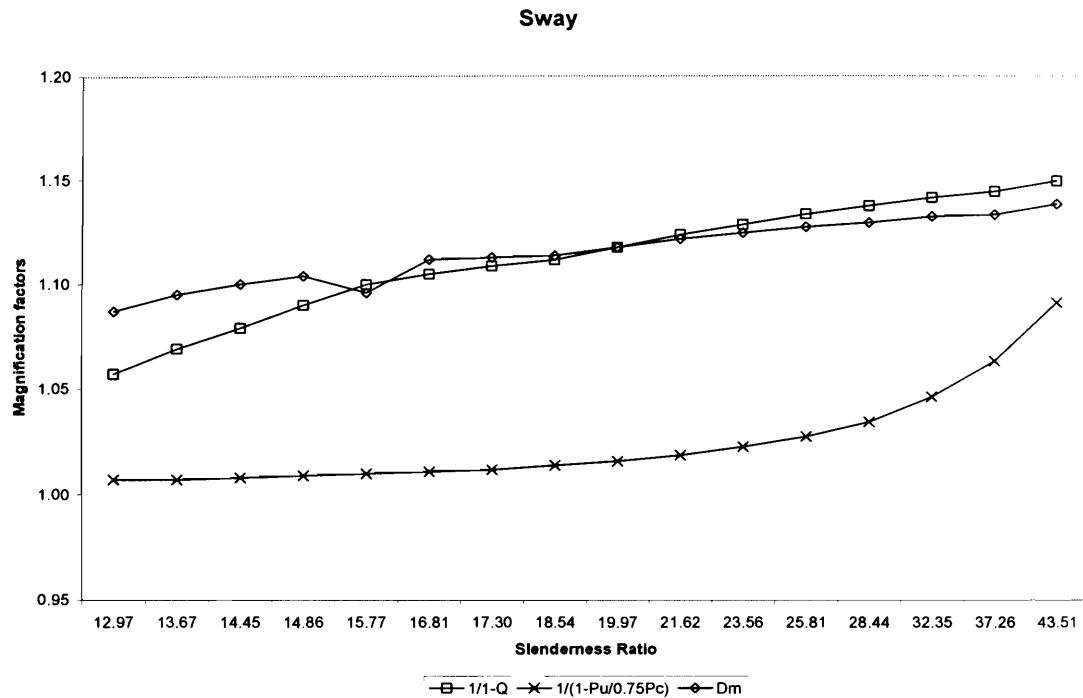

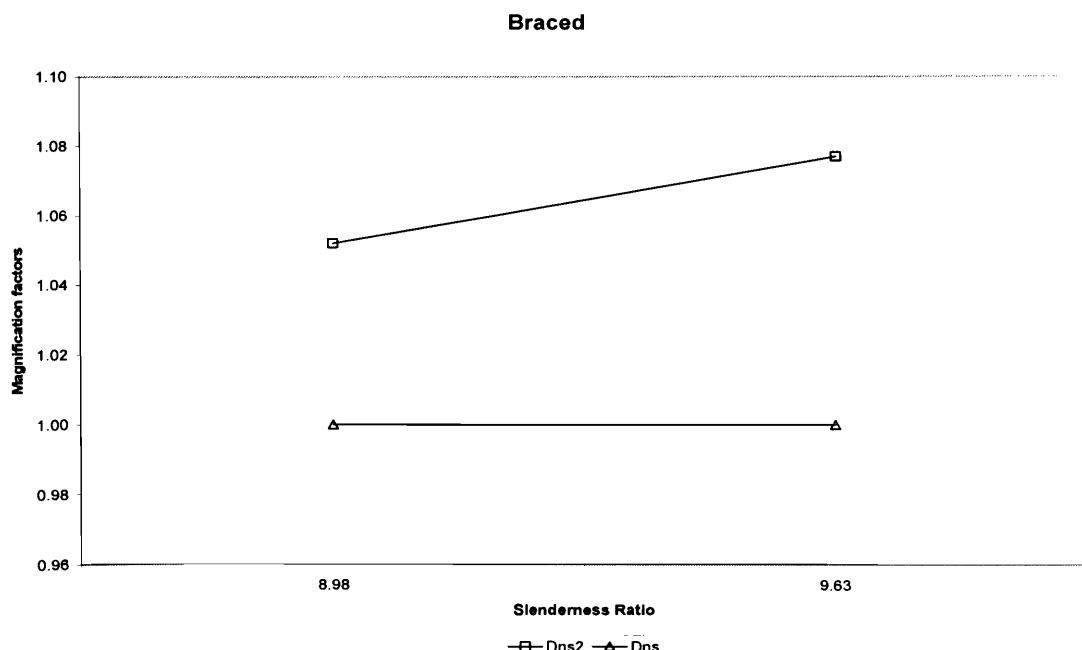

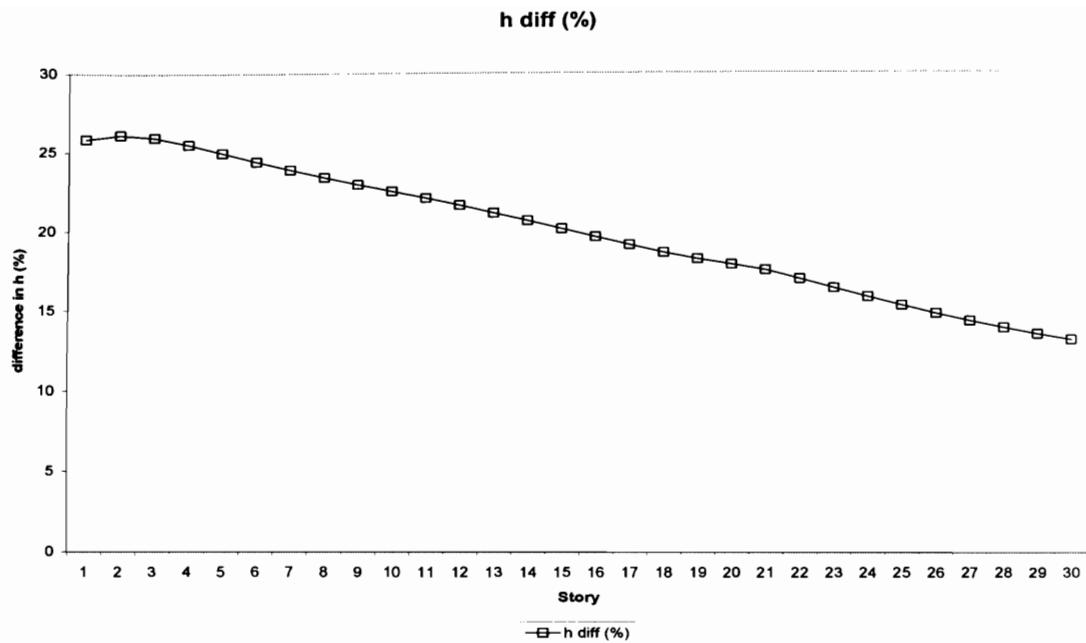

Figure 4.3.7  
ACI sway magnifier factors vs. the ratio of second order to first order moments

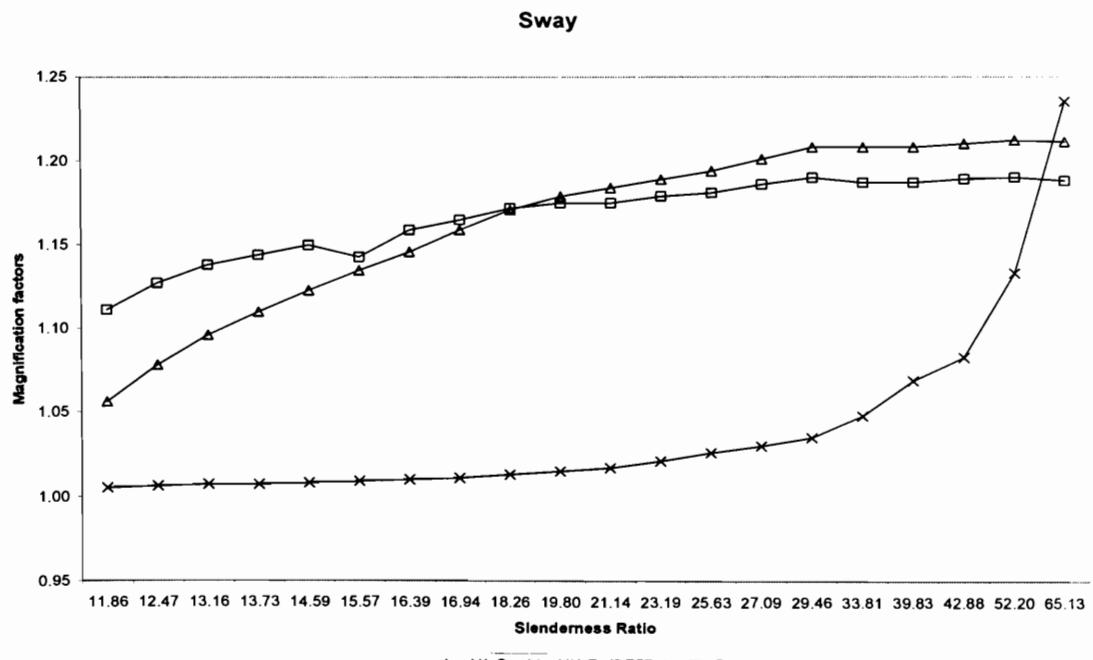

Graph 4.3.8  
ACI non-sway magnifier factors vs. the ratio of second order to first order moments

**Figure 4.3.9**

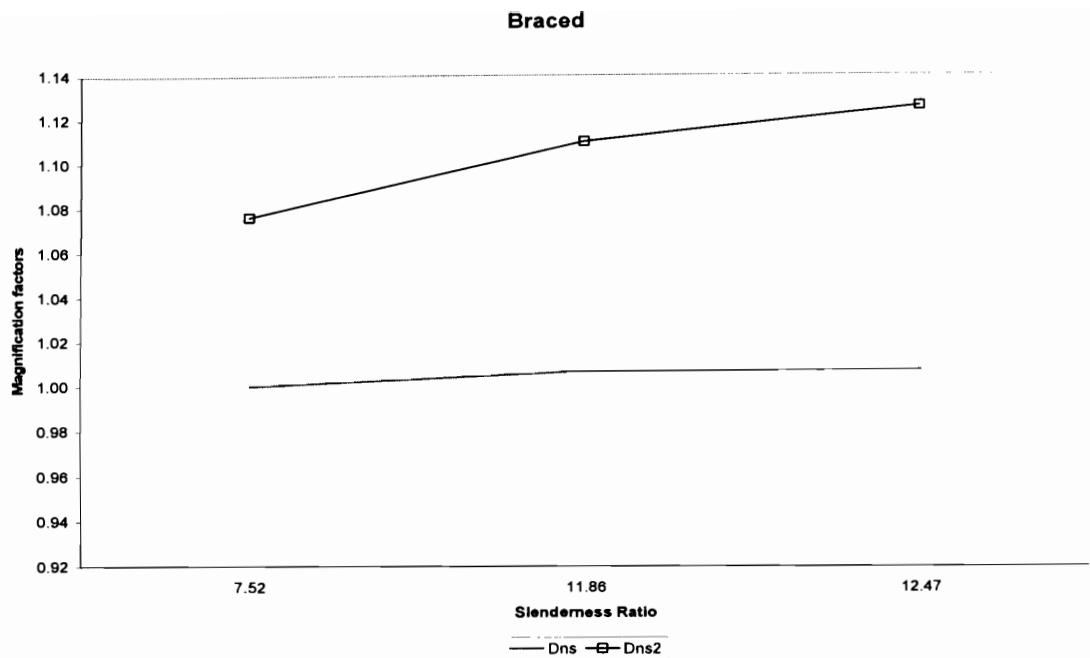

Percentile increase in the square cross- section dimension of a column to equate the un-cracked first order to the cracked second order lateral deflections with respect to story

4) The 36 ft story height building:

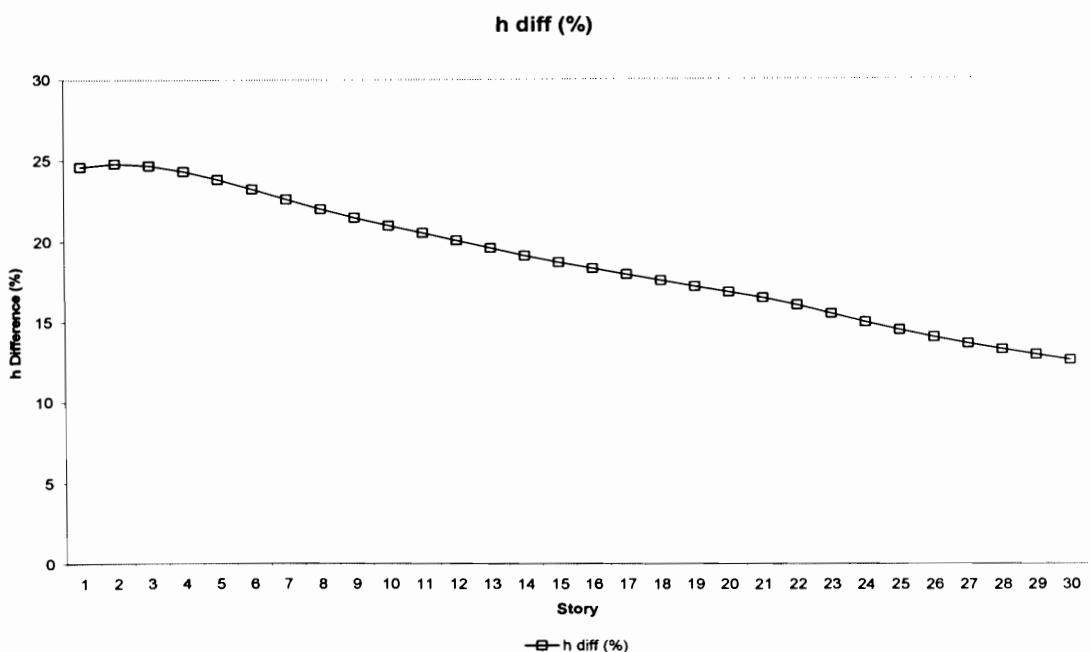

**Figure 4.3.10**

ACI sway magnifier factors vs. the ratio of second order to first order moments

**Figure 4.3.11**  
ACI non-sway magnification factors vs. the ratio of second order to first order moments

Percentile increase in the square cross- section dimension of a column to equate the un-cracked first order to the cracked second order lateral deflections with respect to story for all buildings

## CHAPTER 5

### CONCLUSIONS AND RECOMMENDATIONS

#### 5.1 CONCLUSIONS:

Conclusions are drawn with reference to the set of graphs developed for each building; the conclusions are addressed and compared to the ACI Code recommendations in three main aspects (non-sway moment magnification factor, sway moment magnification factor and cracked/un-cracked analysis results).

From the braced stories graphs set, it can be concluded that ACI code non-sway modification factor is always less than the actual difference in moments between the first order and the second order analyses. ACI permits a 5% difference from the first order to the second order moments and according to ACI, the second order analysis must be performed if the difference exceeds 5%. That means, second order analysis must be performed for the 24 ft, 30 ft and 36 ft story height buildings, this can be seen from figures 4.3.11, 4.3.8 and 4.3.5. All of the buildings except the 18 ft story height have a moment's difference more than the ACI code 5% limit.

The value of the ACI Code non-sway moment magnification factor is calculated using the ACI equation:

$$\delta_{ns} = \frac{C_m}{1 - \frac{P_u}{0.75P_c}} \geq 1.0 \quad (10-9)$$

The (0.75) factor, according to ACI Code:

**R10.12.3** — The  $\phi$ -factors used in the design of slender columns represent two different sources of variability. First, the stiffness reduction  $\phi$ -factors in the magnifier equations in the 1989 and earlier codes were intended to account for the variability in the stiffness  $EI$  and the moment magnification analysis. Second, the variability of the strength of the cross section is accounted for by strength reduction  $\phi$ -factors of 0.70 for tied columns and 0.75 for spiral columns. Studies reported in Reference 10.35 indicate that the stiffness reduction factor  $\phi_K$ , and the cross-sectional strength reduction  $\phi$ -factors do not have the same values, contrary to the assumption in the 1989 and earlier codes. These studies suggest the stiffness reduction factor  $\phi_K$  for an isolated column should be 0.75 for both tied and spiral columns. The 0.75 factors in Eq. (10-9) and (10-18) are stiffness reduction factors  $\phi_K$  and replace the  $\phi$ -factors in these equations in the 1989 and earlier codes. This has been done to avoid confusion between a stiffness reduction factor  $\phi_K$  in Eq. (10-9) and (10-18), and the cross-sectional strength reduction  $\phi$ -factors.

In the 1989 and earlier codes, the moment magnifier equations for  $\delta_b$  and  $\delta_s$  included a stiffness reduction factor  $\phi_K$  to cover the variability in the stability calculation. The second-order analysis method is based on the values of  $E$  and  $I$  from 10.11.1. These lead to a 20 to 25 percent overestimation of the lateral deflections that corresponds to a stiffness reduction factor  $\phi_K$  between 0.80 and 0.85 on the  $PA$  moments. No additional  $\phi$ -factor is needed in the stability calculation. Once the moments are established, selection of the cross sections of the columns involves the strength reduction factors  $\phi$  from 9.3.2.2.

Based on the results of this research, we can recommend using lower values for the stiffness reduction factor for the non-sway moment magnification factor in *ACI* equation (10-9). It will be more reasonable to use  $(I_{cr}/I_g)$  ratio, which is actually the stiffness reduction factor, instead of using the (0.75) value. That is due to the variation in the amount of cracking in the structural element in each story.

Referring to figure 4.3.13, this research shows that till about two-third of the building height, the extent of cracking in the structural elements is about 0.42 and after that (the rest of the upper stories) the amount of cracking starts to decrease to about 0.8.

In the ACI code equations, the stiffness reduction factor used for calculating the non-sway and sway moment magnification factors is the same (0.75). A conclusion can be drawn based on the results this research, the value of the stiffness reduction factor in calculating the non-way moment's modification factor should be around 0.42 till the second third of the building height. For the rest of the building a value of 0.8 can be used.

From figures 4.3.1, 4.3.4, 4.3.7 and 4.3.10, for the two values of the sway moment magnification factor ACI recommends to use:

$$\delta_s M_s = \frac{M_s}{1-Q} \geq M_s \quad (10-17)$$

$$\delta_s M_s = \frac{M_s}{\frac{\sum P_u}{1 - \frac{0.75 \sum P_c}{}} \geq M_s} \quad (10-18)$$

The actual difference in sway moments between the first order and the second order analyses results shows that ACI equation (10-17) is more accurate to be used in calculating the sway moment's magnifier factor.

The conclusion is a cutoff point should be set between the use of equations (10-17) and (10-18). Equation (10-18) can be used for structures containing lateral forces resisting systems (shear walls, braces, etc) and the value of the stiffness reduction factor in equation (10-18) should vary with respect to the story in interest, as suggested earlier.

Equation (10-17) can be used for braced or sway structures, from the graphs it can be seen that for a slenderness ratio greater than 22 equation (10-17) is the most accurate in calculating the sway moment magnification factor.

In the second part of this investigation, using cracked sections in the second order analysis, graphs were drawn to find out how much the sections should be increased to get

the same lateral deflection of the first order un-cracked analysis. The percentage increase was shown for each story for the three buildings. The maximum increase is about 30% and the minimum is around 15%.

It can be concluded that the critical stories in a building are till the second third of the building height. In other words, the first two thirds of a building height should be analyzed using the cracked moment of inertia (modified stiffnesses), since they are most critically affected by lateral deflections of the building. The remaining stories could be analyzed using un-cracked sections (full stiffnesses).

## 5.2 RECOMMENDATIONS FOR FUTURE STUDY:

During the work on this investigation, a set of assumptions were made to simplify the procedure of analysis and design. These simplifications can be investigated further as follows:

First, the building configuration used in this research, one bay by one bay. More complicated configurations can be investigated to add more variation in the results.

Second, all the columns in each building have square cross sections. Other sections can be investigated for columns; this may lead to more specific results regarding other types of cross sections.

Third, no bracing systems (shearwalls, braces...etc) were considered in the buildings. Further investigations can be done for buildings containing lateral loads resisting systems.

Fourth, only 30 story buildings were investigated. Different number of stories can be studied to understand the behavior of buildings having more or less number of stories.
