College of Engineering

This thesis, written by Pattaraphol Batsomboon, and entitled Design and Construction of A Portable Force-Reflecting Manual Controller for Teleoperation Systems, having been approved in respect to style and intellectual content, is referred to you for judgement.

We have read this thesis and recommend that it be approved.

T. C. Yih

Ibrahim N. Tansel

Sabri Tosunoglu, Major Professor

Date of Defense: November 21, 1997

The thesis of Pattaraphol Batsomboon is approved.

Dean Gordon R. Hopkins
College of Engineering

Dr. Richard L. Campbell
Dean of Graduate Studies

Florida International University, 1998
I dedicate this thesis to my mom who has been patiently awaiting this piece of work, to my dad who has not been able to see my achievement, to my sisters and my brother who have always been encouraging and supporting me. Without their support, this thesis would not have been written at all.
ACKNOWLEDGEMENTS

This work is partially funded by the U.S. Air Force, Air Force Materiel Command (Grant No: FY8990-95-00094). This support is gratefully acknowledged.

I wish to thank the past and the current members of the Robotics and Automation Lab: Vittorio Monteverde, Ernesto Romero, Victor DeRossi, Miguel Espina, Ray Reyes, and Igor Kirianov for all the help that they contributed along the way.

I would also like to thank my major professor, Dr. Sabri Tosunoglu, who has been understanding, supporting, and encouraging me from the beginning to the end.
ABSTRACT OF THE THESIS

DESIGN AND CONSTRUCTION OF A PORTABLE FORCE-REFLECTING MANUAL CONTROLLER FOR TELEOPERATION SYSTEMS

by

Pattaraphol Batsomboon

Florida International University, 1998

Miami, Florida

Professor Sabri Tosunoglu, Major Professor

A man-machine system called teleoperator system has been developed to work in hazardous environments such as nuclear reactor plants. Force reflection is a type of force feedback in which forces experienced by the remote manipulator are fed back to the manual controller. In a force-reflecting teleoperation system, the operator uses the manual controller to direct the remote manipulator and receives visual information from a video image and/or graphical animation on the computer screen.

This thesis presents the design of a portable Force-Reflecting Manual Controller (FRMC) for the teleoperation of tasks such as hazardous material handling, waste cleanup, and space-related operations. The work consists of the design and construction of a prototype 1-Degree-of-Freedom (DOF) FRMC, the development of the Graphical
User Interface (GUI), and system integration. Two control strategies – PID and fuzzy logic controllers are developed and experimentally tested. The system response of each is analyzed and evaluated. In addition, the concept of a telesensation system is introduced, and a variety of design alternatives of a 3-DOF FRMC are proposed for future development.

CHAPTER 1

INTRODUCTION

As technology becomes more advanced, machines become more complex and intelligent. For instance, industrial robots nowadays are able to make decisions and work autonomously. However, for some of the tasks found, for instance, in nuclear waste cleanup operations or in space, even the most intelligent autonomous robot cannot perform all the tasks successfully. In order to achieve the goal, humans must be a part of the system.

The concept of “man in the loop” is introduced in the so-called teleoperator system. The purpose of having humans in the system is to guide machines to do the tasks properly since he/she cannot perform these tasks by himself/herself as the environment conditions may be harmful. In some cases, the remote site may be a thousand miles away from the operating station. Therefore, better interface between these two stations is a must to carry out many operations safely and reliably.

1.1 Teleoperator Systems

Teleoperation is a general term that refers to a human-machine remote control system. The system usually consists of two robot manipulators that are connected in such a way as to allow the human operator controls one of the manipulators (the master arm)
to generate commands which map to the remote manipulator (the slave arm). A teleoperator system generally consists of a manual controller, control hardware/software, sensory feedback, and a remote manipulator. Teleoperation tasks are distinguished by the continuous interaction between a human operator, teleoperator system, and the environment as illustrated in Figure 1-1.

![Figure 1-1. Information Flow in Teleoperation Systems](image)

The main function of the teleoperator system is to assist the operator to perform and accomplish complex, uncertain tasks in hazardous and less structured environments such as space, nuclear reactors, and underwater operations, with ease, comfort, and fidelity. For instance, robotic technologies have been used to inspect, maintain and service nuclear power plants [Tosunoglu and Hamel, 1994]. As a result, the radiation exposure of workers at the plants has been reduced to the lowest possible level [Rochelear and Crane, 1991]. In a typical teleoperator system, the operator receives feedback information that includes aural, tactile, and force feedback. Although the audio channel may be useful to the operator, the sound is often limited from the system [Draper, 1995].
1.2 Telesensation Systems

In past decades, teleoperator systems have been developed to the point where the human operator is able to perceive the feelings as if he/she were in the actual environment. Such a system is also referred to as telepresence. A more recent goal in the development of teleoperation is called telesensation. Telesensation refers to a remote control system that combines the use of computer vision, computer graphics and virtual reality [Terashima, 1994]. The word “telesensation” has also been used in literature to describe a telecommunication system such as teleconferencing where people from different remote locations in the real world are able to hold a meeting or work cooperatively in the same artificial world.

In the field of robotics, the term “telesensation” implies the advanced teleoperator system that provides the operator with sensation feedback by employing the five senses (if possible). As a result, the operator is able to perceive the “feel” of presence at a remote site while he/she is in a safe workstation. The feel of presence can be provided by feedback information such as visual, aural, tactile, and force feedback as represented in Figure 1-2.

Figure 1-2. Feedback Components of a Telesensation System
A flexible programming environment and better integration of human and computer capabilities highlight the advanced teleoperation technology [Schenker et. al., 1991]. The telesensation system as depicted in Figure 1-3 integrates the use of an advanced operator interface, virtual reality unit, force-reflecting manual controller, and sensor-based manipulator to provide the feel of presence at the remote site [Batsomboon et. al., 1996b]. Thus, with the skilled operator and the sophisticated systems, the tasks can be accomplished with the most efficient and effective manner.

![Figure 1-3. A Pictorial Representation of Components in a Telesensation System](image)

### 1.3 Objectives of the Current Research

One of the desired objectives in the development of teleoperator systems is to design and develop a system that provides the operator with the sensation feedback. A force-reflecting manual controller is one of the components in the system that provides
the operator with force feedback. Unfortunately, most of the manual controllers are bulky, complicated and expensive. For the system to be used in a practical situation, the system must be portable, compact, lightweight, easy to use, and easy to manufacture. Other requirements include large workspace, sufficient force reflection and safe design.

In this work, the design and development of a portable force-reflecting manual controller is addressed as a design problem. This includes conceptual design of the system, construction of a testbed, system parameter identification of the testbed, development of control strategies and interface software, system integration, testing and laboratory demonstration.

In order to satisfy the above requirements, the previous works have been investigated for mechanical and control designs. In addition, a survey of mechanical components such as actuator systems and sensors has been conducted to identify compact size, lightweight and high-performance components. The conceptual designs of 3-DOF force-reflecting manual controller are presented while the principle of the force-reflection is demonstrated on a 1-DOF testbed.

The contents of each chapter are summarized as follows:

Chapter 1: The concept of teleoperator and telesensation systems is introduced. Then, the objectives and the scope of this work are outlined.

Chapter 2: Background on force-reflecting teleoperation systems is presented by first listing the history of the previous work in chronological order. Some of these works are reviewed in detail with respect to their mechanical designs. The control strategies of these systems are also presented.
Chapter 3: The components of a force-reflecting teleoperation subsystem are reviewed. These components are divided into three main categories: actuators, sensors, and computers.

Chapter 4: Telesensation system development is presented. This includes three main components of the telesensation system: virtual reality unit (VR), force-reflecting manual controller (FRMC), and graphical user interface software (GUI).

Chapter 5: The 1-DOF force-reflecting manual controller prototype is discussed. This chapter provides information on the system components and setup. In addition, the system parameters are identified in order to obtain a mathematical model for the system.

Chapter 6: Testing of the 1-DOF testbed and evaluation of results are presented. Two control strategies, one based on PID, and the other on fuzzy logic, are developed and tested on the 1-DOF system. The PID represents the traditional, and fuzzy logic more recent controller development efforts. Evaluation is based on the comparison of experimental results to that of numerical simulations.

Chapter 7: The conclusions and recommendations derived from this work, and future work to be conducted are presented.
CHAPTER 2

BACKGROUND

In this chapter, the milestones in teleoperation system development are presented, and some of the previous teleoperation system designs are reviewed.

2.1 Previous Works

- 1947. Ray Goertz and his group developed the first manual controllers at the Argonne National Laboratory (ANL). The system was mechanically and electrically connected.
- 1948. Ray Goertz and his companies developed the Model-1 bilateral mechanical master-slave manipulator.
- 1948. General Mills produced the Model-A unilateral manipulator in which the arms and hands were driven by switch-controlled motors rather than by direct mechanical or electrical linkage to the operator.
- 1954. Ray Goertz and his group developed the first bilateral force-reflecting servo-manipulator.
- 1958. First mobile manipulator with TV was built at ANL. This teleoperator was called a “slave robot.”
1958. Ralph S. Mosher and coworkers at General Electric produced a manipulator which included force reflection and an exoskeleton master controller called the Handyman Electro-Hydraulic manipulator.

1961. The first manipulator was fitted to a manned deep-sea submersible when a General Mills Model 150 manipulator was installed on the Trieste.

1966. Jones and Thousand developed one of the first dextrous master manipulators using pneumatic bladders.

1970’s. NASA developed an advanced teleoperator system. The Remote Manipulator System (RMS) was developed for the space shuttle.

1977. Teleoperator System Corporation created a force-reflecting manipulator called SM-229, which was designed to be used in a nuclear plant.

1970’s. The Center for Intelligent Machines and Robotics (CIMAR) of the University of Florida developed a 6-DOF nine-string manual controller and a 4-DOF force-reflecting planar controller.

1980. Hill and Salisbury at Stanford Research Institute (SRI) joined by Bejczy at Jet Propulsion Laboratory (JPL) developed a bilateral 6-DOF force-reflecting manual controller.

1980’s. Oak Ridge National Laboratory (ORNL) developed the M-2 Maintenance System and the Advanced Servomanipulator (ASM) master-slave, force-reflecting teleoperator system for the use of maintenance in a nuclear plant.
• 1980’s. Whitney at Draper Laboratory at MIT designed and developed a hand controller which implemented resolved motion rate control.

• 1985. Tesar and Tosunoglu at the University of Texas at Austin developed a 6-DOF nine-string force-reflecting manual controller and a 3-DOF spherical force-reflecting shoulder controller.

• 1985. Landsberger and Sheridan developed a parallel-structured arm using cables in tension and a single passive compressive spine.

• 1992. Rutgers University CAIP Center developed portable I/O device called Rutgers Master.

• 1993. German Space Agency (DLR) developed the first space telerobot called “Rotex Experiment.”

• 1993. EXOS Inc. developed the first commercial systems designed for virtual object manipulation called Touch Master and SAFIRE Master.

• 1993. MIT Artificial Intelligence Laboratory developed the PHANToM Master which was designed for virtual force feedback. The system was made available commercially.

2.2 Force-Reflecting Teleoperation System

In a force-reflecting teleoperation system, the operator uses the manual controller to direct the remote manipulator and receives visual information from a video image and/or graphical animation on the computer screen. A virtual reality unit may be provided to improve perception. While the input motion moves the remote system, forces experi-
enced by the system are reflected at the manual controller, so that the operator feels the forces acting on the system.

Force reflection is most helpful when other sensory feedback such as vision is absent [Draper et. al., 1987]. In such situations where there are dust or gases involved or when the environment is dark, viewing by television cameras is difficult or almost impossible. The force reflection becomes the most important information for the operator to complete the tasks. The operator with force reflection tends to make fewer attempts to complete a given task than the operator who receives no force reflection [Draper, 1995].

2.2.1 Mechanical Design of Force-Reflecting Manual Controllers

The architectures of force-reflecting manual controllers can be divided into two main categories: serial and parallel. Most of the force-reflecting manual controllers use a serial structure because of its design simplicity and large workspace. However, the parallel structure is a promising design in some aspects. The parallel design allows the actuators to be located on the fixed base. Thus, it provides higher stiffness and better precision [Batsomboon and Tosunoglu, 1996a; Conklin and Tosunoglu, 1996]. In addition, parallel mechanisms tend to be more compact than serial mechanisms. Some of the well-known serial- and parallel-structured manual controllers are reviewed below.
Teleoperator System SM-229

In 1977, Teleoperator System Corporation developed a bilateral force-reflecting servo master-slave manipulator called SM-229. It had seven degrees of freedom with a 3.7 m³ workspace. It was designed to serve the requirements of a variety of new installations in nuclear plants. Conceivably, the SM-229 was the first member of a family of force-reflecting electric master-slave manipulators designed to be produced commercially and maintainable [Martin and Kuban, 1985].

Bilateral Force-Reflecting 6-DOF Manual Controller

In 1980, Jet Propulsion Laboratory (JPL) and Stanford Research Institute (SRI) developed a universal, bilateral force-reflecting 6-DOF manual controller [Kim, 1991]. The design effort was to minimize friction, backlash and inertia at the handgrip. The system used the cable/pulley-based counter-balancing and power transmitting mechanism which was capable of generating a force up to 35 oz at the handgrip. In addition, a counterbalance assembly was included in the system to reduce gravitational effects [Bejczy and Salisbury, 1980].

Handyman

The Handyman electrohydraulic manipulator was developed by General Electric company in 1985 [Kim, 1991]. The system includes articulated fingers and an exoskeleton force-reflecting master arm. However, the Handyman did not prove to be practical for several reasons. One of the biggest factors was the limitation of the technology at that
time. Other factors included its large size and overall reliability [Mosher and Wendel, 1960].

**Remote Manipulator System (RMS)**

In the 1970’s, NASA developed the Remote Manipulator System (RMS) for the space shuttle [Kim, 1991]. The system uses two 3-DOF hand controllers: one for translational motion and the other for rotational motion of the end effector [Ravindran et. al., 1984]. The controllers do not reflect forces experienced by the RMS. The RMS primarily uses a resolved unilateral rate control of the individual joints; hence, it essentially controls only position of the remote system.

**Maintenance System (M-2)**

The Model M-2 Maintenance System was developed at the Oak Ridge National Laboratory (ORNL) in an effort to improve remote manipulation technology for nuclear fuel reprocessing and other remote applications [Martin and Kuban, 1985]. The system consists of two force-reflecting master controllers for two servomanipulator arms, television viewing, lighting and auxiliary lifting capabilities. The touch-screen system was used as an interface between the operator and the remote manipulators. The features include force ratio selection, camera/lighting control and system status diagnostics.

**Advanced Servomanipulator (ASM) System**

This remote maintainable force-reflecting servomanipulator system was also developed at ORNL [Martin and Kuban, 1985]. The main objective of the ASM was to use it in reprocessing maintenance which required reliability, radiation tolerance and corrosion resistance. The ASM uses eight remotely replaceable module types where each
module weighs less than 23 kg so that they can be carried by another ASM. The servo-
manipulator used torque tubes which provide a payload capacity of 23 kg. One of the
main differences of the ASM from the traditional system is the anthropomorphic (elbow-
down) geometry. The reason for this was that the system was designed to work on objects
in a vertical plane.

**MEL Master Arm**

The Mechanical Engineering Laboratory of the Ministry of International Trade
and Industry (MITI) had developed the MEL master arm for teleoperation and VR appli-
cations [Kotoku et. al., 1989; Kotoku et. al., 1992]. The workspace is about 40 × 42 × 30
cm and able to provide force feedback up to 20 N in translation and 0.4 N·m torque about
the arm handle. Unlike the 6-DOF JPL universal master arm, the MEL arm has four de-
grees of freedom and uses direct-drive AC brushless motors. A SUN 25-MHz Sparc
workstation is used to display VR simulations.

**Dextrous Arm Master**

The Dextrous Arm Master has a total of ten degrees of freedom, seven DOF in the
arm and three DOF at the wrist [Jacobsen et. al., 1991]. Each joint contains a hydraulic
actuator/servo valve, load cell, and a high-precision potentiometer. The system has a rela-
tively high bandwidth of 100 Hz at the wrist and provides a maximum torque of 5.5 N·m
at the hand (97.7 N·m at shoulder and 22 N·m at wrist). The system was originally devel-
oped by SARCOS Co. for underwater teleoperation applications [Burdea, 1996].
**FREFLEX Master**

The 7-DOF electrical Force REFlecting EXoskeleton Master is developed for research at the Wright-Patterson Air Force Base [Burdea, 1996]. The system provides 25 N of force feedback at the handgrip using cables to transmit forces to the user’s hand. However, due to the large inertia, gear friction and backlash, the system bandwidth is limited to 20 Hz though the control bandwidth is about 200 Hz.

**Kraft KMC-9100**

The Kraft KMC-9100 force-reflecting hand controller shown in Figure 2-1 is produced by Martin Marietta/Kraft. This compact system has six degrees of freedom and is able to reflect forces up to 5 pounds when fully extended. It is kinematically similar to the human arm which creates an intuitive relationship between the operator’s movements and those translated to the manipulator. It was intended to be used for the Flight Telerobotic Servicer (FTS).

![Figure 2-1. Kraft Manual Controller](image_url)
Cybernet System PER-Force

Two versions of PER-Force, 3 DOF and 6 DOF, have been produced by the Cybernet System Corporation. The 3-DOF version consists of three 30 oz-in brushless DC motors. It is capable of reflecting a maximum force of 9 pounds and yet the joystick unit weighs only 4.5 pounds. The 6-DOF version (Figure 2-2) incorporates three linear axes with the position resolution of 0.0003” per location and three revolute axes with 1/90 degree or 40 seconds position resolution. The unit was originally designed for the Space Station. Both versions can be controlled by IBM, VME or Macintosh-compatible computers.

![Figure 2-2. PER-Force 6-DOF Force-Reflecting Manual Controller](image)

PHANToM

The Personal Haptic Interface Mechanism, PHANToM, is the three-DOF “thimble-gimbal” desktop device that provides a force-reflecting interface between a human
user and a computer [Massie and Salisbury, 1994]. The system shown in Figure 2-3, which has been developed at the MIT Artificial Intelligence Laboratory, enables the user to manipulate and feel the virtual objects. PHANToM consists of three DC brushed motors with encoders and the human finger. The encoders are used to track the operator’s finger tip in the x, y, and z coordinates while the motors control the forces exerted upon the operator. The system is able to provide a maximum force reflection of 10 N and continuous force of 1.5 N.

![Figure 2-3. PHANToM System](image)

**Parallel-Structured Force-Reflecting Manual Controller Designs**

**Stewart Platform**

The Stewart platform (Figure 2-4) was first introduced by Stewart [Kim, 1991]. It has six degrees of freedom and uses all six actuated prismatic joints. The prismatic actuators are usually not backdrivable, but with the addition of a load cell in the actuators,
the Stewart platform can be made backdrivable and able to provide force feedback. This design has attracted many teleoperation system developers because of the high force feedback produced by the system [Burdea, 1996].

![Stewart Platform](image)

**Figure 2-4. Stewart Platform**

**Haptic Master**

Based on the Stewart platform design and an earlier prototype developed by Iwata at the University of Tsukuba, Nissho Electronics Co. of Japan has produced Haptic Master [Burdea, 1996]. Haptic Master has six degrees of freedom but uses nine actuators to eliminate kinematic singularities in the workspace. The system workspace is a 40-cm-diameter sphere centered on the mobile platform and can provide a maximum of 69 N of force feedback.

**Nine-String Force-Reflecting Six-DOF Manual Controller**

Nine-string six-DOF manual controller (Figure 2-5) has been developed at the University of Texas at Austin [Lindemann et. al., 1987]. The system is capable of re-
flecting forces up to ten pounds by using nine actuators to control nine string tensions. In addition, three constant-pressure air cylinders are used to provide constant compression forces where the strings cannot provide the force needed. The workspace has no singularities, and because the motion of each string is measured by a potentiometer, the computational burden is reduced. On the other hand, the system is rather bulky and has relatively high friction from the pneumatic cylinders.

Figure 2-5. Six-DOF Nine-String Manual Controller

Three-DOF Spherical Shoulder Manual Controller

A three-DOF spherical shoulder manual controller (Figure 2-6) has also been developed at the University of Texas. This system has almost the same features as the nine-string controller except that it has only three degrees of freedom. As in most parallel-structured mechanisms, the spherical shoulder allows the location of heavy actuators on the base; thus, increasing the payload capacity. However, because each actuator is inte-
grated with a harmonic drive system with a 60:1 gear ratio, the system exhibits high magnitudes of friction, backlash and inertia forces due to the high gear-ratio reducers in the actuator modules [Kim, 1991].

![Three-DOF Shoulder Manual Controller](image)

Figure 2-6. Three-DOF Shoulder Manual Controller

**Space Interface Device for Artificial Reality (SPIDAR)**

SPIDAR used stringed force-feedback interface as the 6-DOF Texas Nine-String manual controller, but it is simpler and more compact [Burdea, 1996]. SPIDAR was developed by Ishii and Sato at the Tokyo Institute of Technology [Ishii and Sato, 1993]. The system initially had four strings attached to a cap worn on the user’s pointer, but later had eight strings to provide force feedback to thumb and pointer finger. To manipulate virtual objects, SPIDAR II was created. Two SPIDAR IIs were combined on a single support frame to allow the user to operate with both hands. Each hand had a 30-cm-diameter spherical workspace within a planar 120 × 60 cm structure.
FIU Three-DOF Manual Controller

The conceptual design of a three-DOF force-reflecting manual controller, which was developed at Florida International University, is shown in Figure 2-7. The system utilizes a direct drive setup which eliminates the need of intermediate transmission elements such as gears or belts. As a result, it promises zero backlash and virtually no friction. The system consists of three powerful, small rare-earth permanent magnet brushless DC motors which provide a maximum reflected force of five pounds. The design is expected to be one of the most compact three-DOF manual controllers.

Figure 2-7. FIU 3-DOF Force-Reflecting Manual Controller Design

Recently, telerobotic systems and VR technologies have attracted many researchers in the field of medication, especially for surgical training [Burdea, 1996]. Interactive CD-ROM anatomy and surgical training systems have been available commercially. Table 2-1 briefly describes some of the systems. The detailed description of these systems can be found in [Burdea, 1996].

### 2.2.2 Force-Reflecting Controller Design

The control method of the force-reflecting teleoperation system can be divided into two categories: position-position and position-force [Vertut and Coiffet, 1986]. In the position-position method, the difference of the position between the master arm and the slave arm is used to derive the force feedback. This method is used when the two arms have similar kinematics configuration. For dissimilar arms, the position-force method is used. This method uses direct force feedback rather than position error. The external force that the slave arm experiences is measured by a force/torque sensor which is attached to the wrist of the robot. This force is reflected to the operator hand via the master arm according to the force scaling factor. Since this feedback signal is more precise than the po-
sition error signal, the position-force method can provide better force-reflection characteristics to the operator [Cha et al., 1996].

For the position-force scheme, two control modes - position and force, must be implemented in the control loops. Whitney notes that when a force is exerted by the end-effector on the environment, a force control mode is perpendicular to the environment and the position control mode can be exerted to the environment tangentially [Whitney, 1977].

Figure 2-8 depicts the concept of an open-loop control in the position-force method. This control strategy is called open loop because each of the position and force reflection commands is fed in a forward (open loop) sense. For instance, when the force feedback feature is implemented, the reflected force will be adjusted by comparing the difference between the desired and actual values as shown in Figure 2-8. Such an open-loop scheme may not provide satisfactory results because the control system is unmodelled for dynamics, friction, backlash, delay, etc., between the teleoperator and remote system. As a result, the system may become unstable.

![Diagram of Open-Loop Control of a Teleoperation System](image)

**Figure 2-8. Open-Loop Control of a Teleoperation System**

22
A more sophisticated control scheme, the closed-loop control, is shown in Figure 2-9. The output of the remote system is directly fed back to the input of the manual controller while the local feedback loops still remain in the control loop. This closed-loop control accounts for dynamics, friction, backlash, delay and perhaps, beam damping which is an important parameter for the long-reach manipulator [Jansen et. al., 1991].

![Diagram of Closed-Loop Control of a Teleoperation System](image)

**Figure 2-9. Closed-Loop Control of a Teleoperation System**

One of the crucial issues in the force-reflection control system that needs to be addressed is time delay. The round-trip delay can be as much as 2 seconds in the deep ocean or 6 seconds in the case of the earth-orbiting space shuttle [Sheridan, 1993]. Under the presence of time delay in the teleoperation system, force reflection becomes troublesome. According to Ferrell's experiments, it is unacceptable to feed force continuously...
back to the operator because the unexpected disturbance can cause the system to be un-\[\text{Ferrell, 1966}\]. Several alternatives have been proposed to deal with the time-
delayed force feedback, such as displaying force feedback in the visual form, feeding the
reflected force to a different master arm, and predicting the force feedback to compensate
for the delay \[\text{Sheridan, 1993}\].

Currently, some of the well-known position-force control methods used for a
force-reflecting teleoperation system are kinesthetic force feedback, shared compliant
control \[\text{Kim et. al., 1992}\] and “telemonitoring” sensory feedback \[\text{Lee and Lee, 1993}\].
These methods provide force feedback except that kinesthetic force feedback has a stiffer
system. In kinesthetic force feedback, the forces sensed by the remote manipulator are fed
back and are reflected through the operator’s manual controller, whereas in a shared com-
pliant control, the human operator shares the control task with the autonomous compliant
control of the remote manipulator. In the telemonitoring control mode, the system con-
sists of a position control with a position error-based force reflection and remote site
compliance \[\text{Lee et. al., 1985}\]. Its control mode basically is under a shared compliant
control but has telemonitoring force feedback.

When there is no significant time delay involved, all three control modes perform
the given task at about the same efficiency. However, under the presence of time delay in
the teleoperation system such as underwater operations or in space operations, force re-
\[\text{Lee et. al., 1985}\]. Its control mode basically is under a shared compliant
control but has telemonitoring force feedback.
mode cannot be operated at time delays above 0.5 to 1 second because of the instability problem [Kim et. al., 1992].

Shared compliant control has been implemented as a new feature added to the force-reflecting telerobot system. In shared compliant control, the human operator controls the compliant robot hand. The compliant hand reduces the contact force between robot manipulator and objects. Thus, it improves smoothness of mechanical contact and safety.

W.S. Kim, B. Hannaford, and A.K. Bejczy at Jet Propulsion Laboratory (JPL) have proven the superiority of shared compliant control over kinesthetic force feedback system [Kim et. al., 1992]. Their experiment demonstrates that shared compliant control is able to perform the task at time delays above 1 second. This is possible because the entire feedback loop remains in the remote side. As a result, time delay in communication does not cause a stability problem. In addition to the time-delay advantage, the completion time is also reduced when shared compliant control is used instead of kinesthetic force feedback [Kim et. al., 1992].

S. Lee and H.S. Lee at the Advanced Teleoperation (ATOP) laboratory of JPL have developed a teleoperator control system called “telemonitoring” sensory feedback [Lee and Lee, 1993]. The control mode consists of position control with position error based force reflection and remote site compliance [Lee et. al., 1985]. Basically, its control mode is under shared compliant control while having telemonitoring force feedback. The experiments have been conducted to evaluate and compare the performance of various manual control methods including conventional force feedback, shared compliant control
and telemonitoring force feedback. The experimental results showed that the telemonitoring force feedback was always ranked first [Lee and Lee, 1993]. They revealed that under shared compliant control mode, the operator tends to make larger positional and/or orientational command errors. This is because the operator does not know how much force on the remote manipulator is shared by the compliant control. As a result, the operator feels uncertain in evaluating commands which causes more erroneous and hesitant control behavior. They also suggest that when the proposed system is compared to the conventional force feedback and shared compliant control, it is expected to perform better where time delay is significant although the experiment is not yet verified.
CHAPTER 3

FORCE-REFLECTING TELEOPERATION SUBSYSTEMS

This chapter primarily reviews some of the components for a teleoperation system. The material covers the major components such as the actuators, transmission systems, sensors, computer hardware, computer interface, and computer software.

3.1 Actuators

Input power for teleoperated systems is provided by hydraulic, pneumatic or electric actuators, each of which is briefly reviewed below.

Hydraulic Actuator

Hydraulic actuators are usually used for large telemanipulators because hydraulic power can generate relatively high forces in a small volume with good rigidity and servo control of position and velocity [Todd, 1986]. Thus, the manipulators can be lightweight, which allows them to carry more weight for the same power output provided by an electric motor. However, one of the biggest problems with hydraulic systems is their tendency to leak oil which is not suitable for most teleoperation applications [Poole, 1989].
**Pneumatic Actuator**

Pneumatic systems are based on the pressure available from compressed air reservoir and their valves are either fully on or fully off, where each actuator stops only at the end of its travel. Therefore, pneumatic actuators are often used only for the gripper of an electric or hydraulic manipulator where its elasticity is useful as it automatically limits the force [Todd, 1986]. In addition, a pneumatic gripper actuator is very light and needs to be connected only by a narrow flexible tube which is easy to feed through complex mechanisms such as a wrist.

**Electric Actuator**

At present, electric actuators represent about 70 percent of all the actuators used in robotics. Some of the advantages of the electric motors that make them more popular in industry are as follows:

- High reliability
- Low friction
- Easily controlled by a computer or a microprocessor
- Compact size, volume and weight with respect to the power output: High Torque/Weight ratio
- Less frequent maintenance requirements
- Precise, responsive, clean and quiet operation
Electric motors can be categorized in several ways, but for the teleoperation applications, the field is further narrowed and only the stepper and servomotors are presented.

**Stepper Motor**

A stepper motor is simple to use and control in an open-loop configuration. Commutation and position are controlled by step and direction pulses. It provides excellent torque at low speeds which is suitable in robot applications. However, stepper motors can cause slippage during rapid acceleration and when overloaded. The error produced by this slippage can go undetected and cause damage. Thus, in order to control an open-loop system accurately, the pulse frequency must be varied during times of acceleration. On the other hand, when driving light loads, stepper motors have resonance effects. It oscillates around the stopped position and overshoots. To eliminate vibration or resonance effects and suppress overshoot, a damping system is required. Generally, a stepper system does not provide any kind of feedback information. Therefore, a feedback device must be added to verify position; otherwise, torque cannot be controlled.

**Servo System**

A servomotor is used in a closed-loop configuration. The servo control systems include those elements that interface with the controller and the manipulator. Each servomechanism has two sensors (one receives signals from and the other sends signals to the controller) that create a closed-loop feedback system. The control system, as a whole, uses data generated by the feedback system to monitor movement. The computer then
performs calculations to determine the next motion and directs the servomechanisms to move accordingly.

Typical servomotors include integrated position and velocity sensors. Unlike the stepper motor with added feedback devices that make the necessary corrections between actual and desired position after the move, the servo motor continuously monitors actual information such as position and velocity, and compares those values to desired values and makes necessary corrections to compensate for any error.

There are two types of DC servomotors: Brush and brushless. Conventional DC motors have brushes and commutators. The main drawback of this type of motor is a maintenance problem. When the motor is loaded, the sliding contact between the brushes and the commutators causes an arc, and both components must be replaced when they wear out.

The other type of DC servomotor is the brushless type. It displays the same torque-speed characteristics as a conventional DC brush motor. Recently, there has been an increasing interest in using brushless motors in high-performance applications. A number of practical advantages accrue from the elimination of the brushes and commutator. The brushless motor has longer life, better heat dissipation and is free of maintenance.

3.2 Transmission Systems

Since an actuator output is typically at higher speeds than needed in teleoperation systems and actuators are too large, heavy and bulky relative to the output power, trans-
mission systems are used. Hence, transmission elements are added to provide the system with higher torque while keeping the actuator systems compact.

Typical transmission components are gears, tendons, and linkages. However, for advanced teleoperator systems, gears are the most common type used because they are capable of carrying larger payloads and are more accurate than the other two types mentioned above. The harmonic drives and direct-drive systems have also become popular in industry.

**Gears**

Gears are the most common transmission elements because they can transmit large torques with the use of small size motors. Hence, the systems are compact. However, many problems are encountered when using gearing systems. One of the biggest problems is backlash which causes inaccurate motion control. In addition, when designing a gearing system, the designer must consider the mechanical nonlinear properties such as friction and deflection.

**Harmonic Drives**

Harmonic drives, which use a special gear architecture, are usually used with revolute joints. A number of advantages of harmonic drives over the other transmission elements can be summarized as follows: high gear ratios, compactness, and almost zero backlash. These features increase accuracy. However, because of the tight mechanism, contact area between the teeth is considerably larger which causes high friction.
Direct Drive

Recently, the development of motors has been greatly improved. With these improvements, motors have been able to provide high torques with relatively small sizes. This advantage allows the designer to develop the system by coupling the system's load directly to the motor without the use of transmission elements such as belts or gears. Such a system is known as direct drive. The elimination of the intermediate transmission provides the system with better accuracy since there is no friction or backlash introduced to the system. The reliability of the system is also improved because a smaller number of components is used. However, one of the main problems that direct-drive motors encounter is overheating. As the intermediate transmission elements are eliminated, the load must be carried by the motor entirely and directly. Thus, the motor must be able to exert a large amount of continuous torque with very efficient cooling; otherwise, the motor may be burned out.

3.3 Sensors

In telesensation systems, the goal is to provide the operator with the feeling of presence at the remote site. To accomplish this, various types of sensors must be used in the system. The sensors must be able to reproduce faithfully those physical properties of the working environment, and they must be sufficient in providing sensational feelings to the operator so that he/she can complete the required jobs with relative ease [Johnsen and Corliss, 1971]. For the purpose of this work, the sensors are divided into four main categories.
3.3.1 Position Sensing

Encoders

Encoders are used to control position by translating mechanical motion into electronic signals. There are a number of types used, but the most widely used are the optical encoders. The encoder consists of a glass and a mylar or metal wheel with alternating clear and opaque stripes. The positions are monitored by the detection of the stripes by optical sensors to generate the output position in digital form. Two types of optical encoders used are incremental and absolute encoders.

- Incremental encoder: This form of optical encoder produces a pulse for a given increment of shaft rotation. Shaft angular rotation is determined by counting the encoder output pulses.

- Absolute encoder: An absolute encoder has a number of output channels. Each position of the shaft is determined by the unique code. As a result, absolute encoder is preferable for applications that require high accuracy.

Resolvers

Resolvers are electromagnetic feedback devices which convert angular shaft position into analog signals. These signals can be processed in various ways such as with a resolver-to-digital converter to produce digital position information. Resolvers are rugged devices compared to encoders, but they are relatively noise insensitive and able to transmit data over long distances.
3.3.2 Speed Sensing

Tachometers

Tachometers are electromagnetic sensors which generate an output voltage signal proportional to shaft velocity. A small permanent magnet DC motor can be used as a tachometer. The manufacturers often include a tachometer in DC servo motors so that they are able to produce low-cost and high-performance products.

3.3.3 Force and Torque Sensing

Force and Torque Sensors

Force sensors measure the reaction forces between the object and the environment; thus, they are classified as external sensors. On the other hand, joint torques are sensed with internal sensors. In order to obtain accurate results from force sensors, they should be installed directly on the gripper, instead of between the wrist and the end-effector. This is because the weight of the end-effector can take up most of the dynamic range of the sensors.

Strain gauges are usually the basic sensing elements of force sensors. A torque sensor has the transducer in a sealed unit and includes a microprocessor unit to resolve the measurements that are applied to the transducer into six equivalent Cartesian force/torque components. It then gives the output information via a standard interface.
3.3.4 Temperature Sensing

Thermistors

Changes in temperature can be measured and sensed by a device called a thermistor. It responds to changes in temperature by a change of resistance in the sensing element. Thermistors can be as small as 0.005 in. in diameter and react to temperature changes quickly. Thus, they can be used in point sensing. However, the output of thermistors is nonlinear with temperature. As a result, the computer must be able to interpret the output with the response curve of the particular thermistor.

Thermocouples

Thermocouples have been used as temperature sensors for years. They consist of two dissimilar metals which are in thermal and electrical contact. As the temperature increases, the output of the thermocouple increases, but nonlinearly. Thermocouples can be made very small and cover a wide range of temperatures. However, in addition to nonlinear output, thermocouples also suffer from low signal outputs.

3.4 Computer Hardware

3.4.1 Buses

Buses carry and link information between the components or between subsystems. When selecting a bus system, several factors should be considered. Preferable characteristics include [Tooley, 1988]:

- Industry-standard architecture
• High data transfer rate

• Support of a wide range of processors (8-, 16- and 32-bit types)

• Standard size

VME, STE and PCI form the standard buses currently used in control systems.

**VME Bus**

VME bus supports fast data transfer rates and uses a single connector to provide a 16-bit data path. In the case of the extended bus which supports 32-bit address, a second connector is used. However, the VME bus may be considered expensive for simpler applications.

**STE Bus**

One of the advantages of the STE bus is that the bus signals and protocol are standardized. Various processors from different manufacturers can be implemented in the system. Thus, the designer can be confident in interconnecting STE bus products from different companies.

**PC Bus**

Industry-standard PCI specifications have recently emerged and been supported by PC-compatible computers and PowerMacs. Hence, the new systems targeting PC platforms should consider the PCI architecture.
3.5 Computer Interface

An interface represents a connection between a computer and other components in the system. In the field of robotics and telesensation, the computer interface is very important as the control system must be accurate and fast. The computer interfaces discussed here are actuator controllers and A/D, D/A, D/D converters.

3.5.1 Actuator Controller

The controller of actuators can have various control methods. Two of the most popular control methods used in industry today are standalone and bus-based architectures whose main advantages and disadvantages are described in the following sections.

Standalone

This type of controller operates without the need for data or other control signals from elsewhere. A standalone unit usually consists of a keypad for data entry and a simple display device. Since the unit is unique, it has its own commands which vary from manufacturer to manufacturer. Although some of the products include more than 100 commands, it is relatively easy to write elementary programs because the commands are usually word-descriptive.

Bus-Based Systems

Bus-based systems are considered to be very flexible since the designer is open to various options for optimizing the performance without affecting system compatibility. In addition, since the system comes in the form of computer cards, the users are able to keep up with the rapid improvement in technology by replacing or upgrading the old card in-
stead of changing the whole system. Thus, time is conserved and obsolescence is pre-
vented with relative ease. However, one of the disadvantages of the bus-based control 
system is related to the integration between the motion and I/O structure. It is necessary 
to obtain software integration of different programming languages for different cards 
/controllers).

3.5.2 A/D, D/A and D/D Controllers

Conversion between analog and digital quantities can be considered as the heart of 
computer control systems. Since most of the natural parameters such as speed and dis-
tance are analog, in order to use a computer to control the system, it must first convert 
these quantities into digital form using A/D converters. It then does the calculations, con-
verts back to analog signals using D/A converters and then sends the signals back to the 
devices. For some devices such as encoders, the quantities are measured in digital type, 
so D/D converters are used. Some of the most important features when selecting these 
cards are high speed, low noise and low cost [Hnatek, 1976].

3.6 Computer Software

3.6.1 Supervisory Interface Software

The general structure of the software structure is presented in Fig. 3-1. Some of the desir-
able aspects of the interface software are described below.
Menu-Driven Interface

In a telesensation system or an advanced teleoperator system, a friendly graphical user interface (GUI) that supports a menu-driven windows environment is a very important element. This type of sophisticated software enhances the performance of the operator to accomplish the required tasks more efficiently.

Graphics Window

By providing graphics window displays in the telesensation system, the operator is able to interface with the remote system by means of pictorial communications [Kim, 1993]. The purpose of the graphics system is not only for the use of control interface, but
also for off-line task analysis, planning and animation environment for sensor-based mobile robots [Kim et. al., 1993]. The amount of detail and accuracy in the displayed model depend on the fidelity of the system. The fidelity also includes the smoothness of an animated remote manipulator and the update time between the operator’s motions and the simulation’s motions [Kim and Bejczy, 1991]. By using such graphics software, the mobile robotic systems can be designed, developed and operated in a more efficient and reliable fashion.

In the past, the instability of the visual feedback due to time delay can be avoided by the open-loop control strategy called “move and wait,” wherein the operator controls the master arm and waits for the action of the slave system over the round-trip delay time before he/she can issue another command. To enhance the performance of the bilateral teleoperator system, a predictor display is introduced [Sheridan, 1993]. The predictive display technique provides a real-time computer graphics generation and a detailed display of static objects from the delayed video in predicting the robot arm motion before the actual operations occur [Bejczy et. al., 1990].

In May 1993, the telerobotic experiment which involved the Jet Propulsion Laboratory (JPL) as the simulated ground control station and, 2500 miles away, the Goddard Space Flight Center (GSFC) as the remote site was performed using a high-fidelity predictive/preview display technique [Kim and Bejczy, 1993]. The experiment successfully demonstrated that under a time delay of several seconds, this method could be implemented to the system to compensate in real time for the operator’s visual perception of the task.
3.6.2 Joystick Control Software

Position and Force Scaling

This type of joystick control software allows the user to input the scaling values of position and force reflection between the joystick and the manipulator. In the position mode, as the operator moves the joystick a certain distance, the manipulator would move according to the set scaling value. In the force mode, the operator is able to input the scaling value of reflected force at the manual controller. For instance, when the robot experiences a certain amount of forces, the magnitude of the reflected force is scaled by the operator. This is especially important to prevent fatigue. This flexibility makes it possible to accomplish various tasks at any level of delicacy.

Rereferencing

As the operator moves the joystick, the manipulator moves a certain distance. However, in order to move the manipulator further, the operator must define a reference point so that he/she can make further joystick movements. This is accomplished by temporarily suspending the joystick/remote system connection, moving the joystick to a desirable reference position within its workspace and then establishing the connection with the remote system. This can be achieved by placing a connect/disconnect toggle switch on the joystick.

Joystick Mechanism Input-Output and Force Equations

The joystick input-output motion equations and force reflection equations must be written and carried out by special software. This software computes the forward and inverse kinematic analysis of the manual controller and remote manipulator. These equa-
tions should be written as efficiently as possible so that they can be used in real-time computer control.

### 3.6.3 VR Control Software

One of the main advantages in implementing VR control software in a telesensation system is that VR is capable of moving the human-robot interface to a new intuitive and user-friendly level [Davies, 1993]. The interaction between human and computer is much more perceptive than that of using a mouse to change the view in a flat screen display. In addition, operators become familiar with the environment rapidly and require little instruction in how to use the system. In designing the VR control software, a main requirement is that the tracking of the user’s head must be accurate in terms of position and orientation.

**Latency and Update Rate**

Aside from the accurate tracking, the prime considerations of the system designer are minimizing latency and maximizing update rate. The software must be able to modify images rapidly and keep up with the user’s head movements [Sheridan, 1995]. Both parameters are the indication of whether a VR system will serve as a useful device or frustrate the user [Vince, 1995].

**VR Input Capability**

The interaction between the operator and the VR system can be made through an immersive stereo viewer and voice input. An example of such a system has been developed at ACML for application in the cleanup of massive Underground Storage Tanks
(UST). This system uses audio feedback to continuously guide the operator and to provide command confirmation [Miner and Stansfield, 1994].

3.7 Summary

A typical teleoperation system consists of many components. Depending on how these components are classified, actuators, transmission systems, sensors, and computer systems are always parts of such a system.

The types of actuators used in robotic systems are determined largely from the type of applications. Hydraulic actuators are generally used for heavy-duty applications such as under-water operations whereas most industrial robot systems use electric actuators for clean, precise and quiet operations. Also, a brushless DC servomotor is preferred if maintenance is minimal. As for pneumatic actuators, they are commonly used in the gripper mechanism because of their lightweight.

Transmission systems, such as gears and linkages, are used to reduce the load carried by the actuators. Gears are the most common transmission elements since they can transmit large torques, but the system will sustain friction and backlash. A more compact design is harmonic drives which provide high gear ratios and almost zero backlash. Nevertheless, harmonic drives suffer from friction because of the tight mechanism.

Sensors are also important elements of the system. They provide feedback of the system to the operator. Position feedback can be achieved by using encoder (incremental and absolute) or resolver whereas velocity feedback is available through the use of tachometer. Force and torque sensors provide force feedback through the operator by at-
taching the device at the wrist of the robot. In addition, with the use of thermistors or thermocouples, the environment temperature can be perceived at the operating site.

Computer systems are always a major factor of any teleoperation systems. Computer hardware such as system bus which carries and link information between the components or between subsystems must be carefully selected. Preferable characteristics are high data transfer rate and standard size. The standard buses used in control systems are usually VME, STE, or PCI.

An actuator controller, and A/D, D/A, and D/D converters provide the interface between a computer and other components. Two of the most popular control methods are standalone and bus-based systems where each has advantages and disadvantages over the other. For instance, a standalone system is simple to use but incapable of handling the changes of configurations while bus-based systems are flexible but must use the software compatible with the cards.

The computer software in the teleoperation system is divided into three parts. (i) supervisory interface software: This level consists of menu-driven interface and graphics window to provide the operator with a friendly user interface. (ii) joystick control software: The position and force scaling, rereferencing, and joystick mechanism input-output and force equations are included in this level. This level attempts to provide the operator with all the parameters and options to control the remote system. (iii) VR control software: The software must minimize latency and maximize update rate and provide the input capabilities such as voice input so that the VR unit will serve as a useful device, not frustrate the user.
CHAPTER 4

DESIGN AND DEVELOPMENT OF A 1-DOF FRMC

The 1-DOF Force-Reflecting Manual Controller (FRMC) version has been designed and constructed to demonstrate the basic principles of the force-reflecting teleoperation system. The specifications of the system components and the system characteristics are given in this section. In addition, the system parameters are identified in order to construct a mathematical model. This model will be used to test different control methods in the next chapter.

4.1 1-DOF FRMC Components

At this stage, the dimensions of the system is not a concern of the development of the 1-DOF FRMC since the intention here is to establish the necessary connection and to demonstrate the basic principles of the system. Many companies have been contacted to discuss their actuator and controller systems. Though a motor from one company can be used with a controller from the other company, the decision was made to purchase the complete system from a single company. One of the main reasons is that it is relatively easy to establish the connections of the components that come from the same company.
[Tosunoglu et. al., 1996a]. Should any problems arise, they can be resolved with relative ease.

The actuator and controller systems, which included a rare-earth permanent magnet brushless DC servomotor with 1000-line encoder, PC bus-based controller with PID feedback, amplifier, and interface board were, purchased from the Aerotech Company. Aerotech was selected because of its competitive price and suitability of hardware components. Other components comprising the 1-DOF FRMC include force/torque sensor and processor. The industrial robot PUMA 760 is used to simulate the robotic device at a remote site. Table 4-1 provides a summary of the purchased hardware components and software for the 1-DOF FRMC whereas Figure 4-1 shows the system components. The specifications of each item are given in the relevant section below.

Actuator

In the past decade, the technological development of motors has been greatly improved. High-performance motors become smaller and better. This results from using the latest magnet materials which are Samarium Cobalt and Neodymium magnets, also known as “Rare-Earth” magnets. These types of permanent magnet materials are classified as the highest available energy product. Less amount of material is used in producing high-performance motors. Thus, the sizes of the rare-earth magnet motors are relatively smaller than the other magnet material types such as Ferrite or Alnico.

The motor used in the 1-DOF FRMC is made from rare-earth neodymium magnets. Therefore, the dimension of the system is relatively compact. The motor is attached
to a 1000 line encoder. The detailed specifications of the motor and encoder are given in Table 4-2 and 4-3, respectively.

**Amplifier**

The brushless servo amplifier for this 1-DOF FRMC is the model BA20 from Aerotech, Inc. The BA amplifiers can be integrated into a system using three basic configurations; velocity command, current command, and dual-phase command. In the velocity command configuration, the speed of the motor is controlled by the amplifier. A feedback signal from encoder is monitored by the amplifier. From this signal, the amplifier adjusts the velocity of the motor accordingly depending upon the velocity command from the external controller. In this configuration, the amplifier closes and controls the velocity loop. In the current command configuration, the output current to the motor is proportional to the current command input. The advantage to this configuration is the sine and cosine signals sent to the amplifier; therefore, a tachometer is not required. Finally, the dual-phase command configuration is used in the 1-DOF FRMC. In this mode, the differential input, pre-amplifier, and self-commutation circuits are bypassed. The dual-
phase inputs which are sinusoidal are $120^\circ$ out of phase from each other. The third phase is generated by the amplifier. The advantage of this configuration is that it provides the smoothest possible motion.

The specifications of this amplifier are given in Table 4-4.

**Controller**

The UNIDEX 500 (U500) base model is the basic version of the U500 PC bus-based controller from Aerotech Inc. The servo control system includes:

- 24-bit DSP processor
- 0.24 msec simultaneous update rate for all axes
- Lead error correction and multi-dimensional error mapping
- Dual-loop positioning to eliminate effects of VGA backlash and other forms of lost motion

Detailed specifications are given in Table 4-5.

**Position Feedback**
- Resolution – Incremental encoder, times-4 multiplying
- Accuracy/Repeatability - +/- ½ count of multiplied feedback transducer signal

**Motion Types**
- Independent Motions - Point-to-point incremental; target position or velocity profiles; time based; free run
- Coordinated Motions – Advanced queuing and deferred execution features for simultaneous command execution
- Interpolated Motions – Four axis linear interpolation; velocity profiling; corner rounding
- Digitally Geared Motions - 1:1 master/slave; n:n gear ratio for 1 master and up to 3 slaves or 2 masters with 1 slave each
- Trajectory Adjustment – On-the-fly trajectory modification

**Range Limits**
- Position - $2^{47}$ - 1 counts
- Velocity - $2^{15}$ steps/msec
- Acceleration - $2^{15}$ steps/msec$^2$

**Programming**
- Languages - Hard-coded machine tool G-code (RS-274), equivalent BASIC-like and ‘C’ function calls (via software)
- Software Compatibility - ‘C’, Visual Basic, QuickBASIC; 32-bit ‘Quick Libraries’ available for direct DSP manipulation
Interface Board

The BB501 interface board provides the ability to interface the U500 control board to the BA20 amplifier. This board provides two U500 interface connectors, four axes of amplifier and feedback connectors, one joystick port, three I/O connectors, one D/A connector, one brake connector and an external power supply connector. Also contained on this board are several jumpers that permit the BB501 to be configured for different options and hardware.

The BB501 interface board requires +5 V at less than 0.1 A which it obtains through the main signal connector. An additional 5 V supply may be required to power the encoder and limit circuitry if the amplifiers are not capable of supplying the current. If an external power supply is required, it should meet the following minimum requirements.

Current capacity requirement for a typical system is represented in Table 4-6. However, some systems may require higher amperage supplies.

**Force/Torque Sensor**

The force/torque (F/T) sensor model 100M40A-U760 50L200 was obtained from JR3, Inc. It is a six-axis force and torque transducer with a force-measuring capacity of 50 lbs, and a torque-measuring capacity of 200 lb-in. The cylindrical unit is 100 mm in diameter, 40 mm high and weighs 1.4 lb. It has captive bolts which allow direct connection to the Staubli Unimation Puma 760 robot. The 100M40 model uses metal foil strain gages bonded to strain rings as the sensing element which produces linear outputs. It has signal-conditioning electronics integrated into the sensor body. Included in the electronics are amplifiers, and analog to digital converter (A/D), and EEPROM containing calibration data and RS-485 serial drivers. The 100M40 outputs a 2 megabit per second serial data stream which contains complete 6 axis data at 8 kHz and can be read by ISA (IBM-AT) bus receiver/processor.

The ISA-bus receiver uses the cable to provide power to the sensor, as well as to receive the high-speed serial data from the sensor. The ISA-bus receiver requires no external power. It draws power directly from the ISA bus. The receiver uses the following voltage and currents:

- **5 V:** 650 mA typical
- **12 V:** 25 mA typical (without sensor)
- **-12 V:** 5 mA typical (without sensor)

The sensor will also draw anywhere from 200 to 400 mA from the +12 V, and possibly as much as 100 mA from the -12 V.

The ISA-bus receiver uses an Analog Devices ADSP-2105, a 10 Mips digital signal processing chip. This chip has the ability to provide decoupled and filtered data at 8
kHz per axis. Some of the signal processing functions performed by the ISA-bus receiver include: decoupling, coordinate transformation (translation and rotation), low-pass filtering, vector magnitude calculation, maximum and minimum peak capture, threshold monitoring, and rate calculations.

The ISA-bus receiver communicates to the host computer through two 16-bit I/O ports. Using the I/O ports, the host computer reads directly from a dual-port RAM.

The general specifications of this force/torque sensor are given in Table 4-7.

**PUMA 760 Robot**

For the purpose of the experiment and evaluation of the 1-DOF FRMC, the PUMA 760 industrial robot is used to simulate the remote site. The PUMA 760 robot is a member of the Unimate PUMA 700 series robot manufactured by Unimation, a Westinghouse Company, of Danbury, Connecticut (recently newer models produced by Staubli). The robot consists of six revolute joints which are driven by permanent-magnet servomotors. It weighs 640 pounds (290 kg) and has a maximum static payload of 10 kg. The PUMA 760 workspace is 1.25 meters (spherical volume) with the shoulder at the center.
The system software that controls the robot is called VAL. VAL is a high-level language that is specially designed for the use of the Unimation industrial robots. It provides the ability to define the tasks that robots perform either task by task (single line command) or as a complete program. Real-time computations are performed during the actual running of the robot program to convert the stored data to position information.

4.2 System Setup and System Characteristics

The setup of 1-DOF FRMC is shown in Figure 4-2. The principle of the control system can be summarized as follows. First, the joystick is used to control the motion of the robot. The control software reads in the amount of the joystick movement and computes the data according to the operation parameters such as control modes (position or velocity), scaling values for position or velocity and re-referencing parameters which are input by the user.

Forces experienced by the manipulator are received through the Force/Torque (F/T) sensor. The F/T driver receives the signals, processes the data and transmits it to the control software. The control software carries out the calculations such as force feedback scaling, position scaling, etc. Once the calculations are completed, the program sends the data to the controller, U500, which accepts high-level commands. The controller then computes the necessary torque needed and passes the signals as low-level command signals to the interface board, BB501. The interface board BB501 on the other end is connected to the amplifier BA20 which is used to amplify the signal and deliver the power to operate the motor. The motor drives the joystick that is attached directly to the motor.
For the setup shown in Figure 4-2, the system is able to provide a peak torque of 404 oz-in. With the length of the handgrip of 5 in, the 1-DOF FRMC prototype can produce a maximum force reflection of 5 lb. The update rate of the system is approximately 0.002 sec or 500 Hz. Note that the system is set up in the form of direct-drive configuration. Therefore, more force reflection can be obtained by implementing a gear set to the system. However, the system will sustain higher friction and backlash as a result of using a gear system.
4.3 **System Identification**

The main purpose of constructing a model is to predict the output of the system. Also, a mathematical model is a useful tool to prevent damages to the system that result from unexpected system response. In addition, it serves as a means to experiment for various control schemes such as PID, fuzzy logic, adaptive, neural and other emerging controller.

The system identification is the process of estimating a model of a system based on observed input-output data. According to Ljung, a mathematical model can never be used to represent the true description of the system, but rather it can be best regarded as a sufficient description of certain aspects that are of particular interest [Ljung, 1987].

The following are the common procedures that are used to carry out the system identification process [Hsia, 1977].

1. Select a set of candidate models that represents the system to be identified.
2. Apply an appropriate test signal (input) and collect the data (output).
3. Perform the parameter identification to select the suitable model.
4. Perform the model validation.
5. The process ends if the model is valid. If not, another set of candidate models will be selected. Repeat steps 2-4 until the model is valid.

The choice of an identification method and the type of a model depend on the nature of the system and the purpose of identification. Parametric system models are usually more preferable than nonparametric models because modern control theory and system design techniques require the state variable description of the system dynamics [Hsia, 1977]. As for the choices between discrete and continuous models, it is more practical to
estimate the system as a discrete model since digital computers are commonly used to control and store the data in discrete forms. In addition, difference equations are easier to manipulate and identify than differential equations.

For a parametric, single-variable, linear, time-invariant discrete system, the input-output relationship can be represented by an nth order linear difference equation:

\[ y(k) + a_1 y(k-1) + \ldots + a_n y(k-n) = b_0 u(k) + b_1 u(k-1) + \ldots + b_n u(k-n) + e(k) \]  

(4.1)

where \( y(k) \) and \( u(k) \) are the measured output and input data, respectively.

Equation (4.1) can be written as:

\[ A(q^{-1})y(k) = B(q^{-1})u(k) + e(k) \]  

(4.2)

where

\[ A(q^{-1}) = 1 + a_1 q^{-1} + \ldots + a_n q^{-n} \]

\[ B(q^{-1}) = b_0 + b_1 q^{-1} + \ldots + b_n q^{-n} \]

The transfer function of this system is defined by:

\[ G(z) = \frac{B(z^{-1})}{A(z^{-1})} \]  

(4.3)

Equation (4.1) is also referred to as the ARX model (AR refers to the autoregressive part \( A(q^{-1})y(k) \) and X to the extra input \( B(q^{-1})u(k) \)).

The \( a_i \) and \( b_i \) terms of the ARX model are estimated using the least squares estimation method. This method is described as follows [Hsia, 1977].

Equation (4.2) is rewritten as:
Defining the $2n+1$ input-output vector $x(t)$ as

$$x(k) = [-y(k-1), \ldots, -y(k-n), u(k), \ldots, u(k-n)]^T$$

the $n$ parameter vector $\theta$ as

$$\theta = [a_1, \ldots, a_n, b_0, \ldots, b_n]^T$$

Equation (4.4) becomes

$$y(k) = x(k)\theta + e(k) \quad (4.5)$$

This can be set up as a system of $N$ equations (for $k = 1, \ldots, (N+n)$) as

$$y = X\theta + e \quad (4.6)$$

where

$$y = [y(n+1), y(n+2), \ldots, y(n+N)]^T$$

$$e = [e(n+1), e(n+2), \ldots, e(n+N)]^T$$

$$X = \begin{bmatrix}
    x^T(n+1) \\
    x^T(n+2) \\
    \vdots \\
    x^T(n+N)
\end{bmatrix} = \begin{bmatrix}
    -y(n), \ldots, & -y(1), & u(n+1), \ldots, u(1) \\
    -y(n+1), \ldots, & -y(2), & u(n+2), \ldots, u(2) \\
    \vdots & \vdots & \vdots \\
    -y(n+N-1), \ldots, & -y(N), & u(n+N), \ldots, u(N)
\end{bmatrix}$$
Using the vector Equation (4.6), in which \( y \) and \( X \) are given, \( \theta \) can be estimated by means of least squares. This approach was first derived by Gauss. The complete solution is provided below.

The least-squares method states that the estimate \( \theta \) is chosen so that the value of \( \theta \) minimizes the error function \( J \):

\[
J = \sum_{k=n+1}^{N+n} e^2(k) = e^T e
\]

\[
= (y - X\hat{\theta})^T (y - X\hat{\theta})
\]

(4.7)

Upon setting

\[
\frac{\partial J}{\partial \theta} \bigg|_{\theta = \hat{\theta}} = 0
\]

the least-squares estimate \( \hat{\theta} \) can be obtained by:

\[
\hat{\theta} = (X^T X)^{-1} X^T y
\]

assuming that \( X^T X \) is nonsingular.

To obtain sufficiently rich output that contains the maximum information about the dynamic modes of the system, the system must be excited with frequencies that span a wide range. Under these conditions, the parameters can be estimated with high accuracy. For the particular system at hand, the maximum input voltage that can be applied is limited between -10 to 10 volts. To achieve these limits, the system was excited in the open-loop environment by a sinusoidal signal with a frequency of 7 Hz and sampling
time of 0.001 second. Figure 4-3 shows the measured input-output data collected from the system.

Figure 4-3. Input-Output Data Collected from the System

Figure 4-4 shows the comparison of the output obtained from the actual system and from different models that is described by different order systems represented by transfer function in Table 4-8.
Table 4-8. Models Represented by 2\textsuperscript{nd}, 3\textsuperscript{rd}, and 4\textsuperscript{th} Order Systems

<table>
<thead>
<tr>
<th>Model</th>
<th>Transfer Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>2\textsuperscript{nd}-Order</td>

</tr>
<tr>
<td>3\textsuperscript{rd}-Order</td>
<td>( G(s) = \frac{0.01s^2 + 0.001s + 0.008}{s^3 + 2.9438s^2 + 2.9174s + 0.9736} )</td>
</tr>
<tr>
<td>4\textsuperscript{th}-Order</td>
<td>( G(s) = \frac{0.02533s^3 + 0.0473s^2 + 0.0937s + 0.01336}{s^4 + 3.366s^3 + 4.1777s^2 + 2.2397s + 0.428} )</td>
</tr>
</tbody>
</table>

Figure 4-4. Comparison of the Actual System Response with 2\textsuperscript{nd}, 3\textsuperscript{rd}, and 4\textsuperscript{th}-Order Model Outputs
As can be seen, the 2\textsuperscript{nd}- and 3\textsuperscript{rd}-order models produce output that match the actual system output fairly well whereas the 4\textsuperscript{th}-order model tails away at the end. Thus, either the 2\textsuperscript{nd}- or 3\textsuperscript{rd}-order system can be used as a model for this system. For simplicity, the 2\textsuperscript{nd}-order model is used to represent the 1-DOF FRMC prototype system dynamics.

Therefore, the selected model is represented as

$$G(s) = \frac{0.0296s + 0.042}{s^2 + 1.8944s + 0.8950}$$  \hspace{1cm} (4.8)

### 4.4 Model Validation

To verify the accuracy of the model, the servo loop of the U500 controller was numerically simulated on the computer. Figure 4-5 illustrates the U500 servo loop where

- $K_P$ is Proportional Gain
- $K_I$ is Integral Gain
- $K_D$ is Derivative Gain
- $V_{ff}$ is Velocity Feedforward Gain
- $A_{ff}$ is Acceleration Feedforward Gain
- $F_s$ is Sampling Frequency

Further details of the U500 control scheme are discussed in the next chapter.
Figure 4-5. Servo Loop of U500 Controller
The control method of the U500 controller is based on the traditional PID feedback with velocity and acceleration feedforward loops. It uses a dual control loop having an inner velocity loop and an outer position loop. The block diagram was created using the SIMULINK program to represent the servo loop of the U500 controller. Figures 4-6, 4-7, and 4-8 compare the system response between the model and the actual system of different gains represented in Table 4-9. The sampling time in this experiment is 0.001 second whereas the amplifier block is modeled as a gain whose value is set to 100.

Table 4-9. Gains Used in the System Identification Process

Figure 4-6. Comparison of the System Response between the Model and Actual System for the Gain Set ID1
In Figures 4-6 and 4-7, the model does not yield the output that matches exactly with the actual system response. However, it displays similar behavior which is considered as the most important aspect when constructing the model. The discrepancy between the model response and the actual system output can be explained by unmodeled friction
and unmodeled high-frequency, low-magnitude system dynamics. Because the FRMC system is direct-drive and has only one degree of freedom, the friction is minimal and omitted in the model [Batsomboon et. al., 1998]. With a better set of gains, ID3, Figure 8 shows that the model is able to produce the result that closely matches the actual system response. Therefore, it can be concluded that the second-order model obtained in the previous section is sufficiently accurate to represent the actual system to test the performance of various controllers.
TESTING AND EVALUATION OF CONTROL METHODS FOR THE 1-DOF FORCE-REFLECTING MANUAL CONTROLLER

In this chapter, two control algorithms are experimentally tested on the 1-DOF FRMC testbed. These two control methods are (1) the PID feedback with velocity, and acceleration feedforward, and (2) fuzzy logic controller. The response of the system of each of the methods is analyzed and evaluated. Numerical simulation results obtained from the mathematical model are compared with that of experimental data for both types of controllers.

5.1 PID Controller

The PID controller discussed in this section uses the control loops as presented in the previous chapter. The control loop is shown again here in Figure 5-1.
As stated earlier, the control method of the U500 controller is the PID with velocity and acceleration feedforward. It uses a dual control loop having an inner velocity loop and an outer position loop. The system performance can be obtained in two distinct aspects: First, the attempt to obtain the smallest amount of position error that is allowable by pre-defined tolerances and has smooth motion. Second, the attempt to obtain the smallest amount of position error that is allowable by pre-defined tolerances and have minimal settling time with no concern of smoothness of motion. The optimal performance, therefore, would be to combine both aspects.

5.1.1 Simulation of PID Controller

PID controller simulation is performed by developing a C program in an attempt to mimic the PID of U500 controller. Using the mathematical model obtained in the previous section,
\[ G(s) = \frac{0.0296s + 0.042}{s^2 + 1.8944s + 0.8950} \]

the above equation can be written as

\[(s^2 + 1.8944s + 0.8950)Y(s) = (0.0296s + 0.042)X(s) \quad (5.1)\]

Equation (5.1) is transformed to differential equation as

\[ \dot{y} + 1.8944\dot{y} + 0.8950y = 0.0296\dot{x} + 0.042x = u \quad (5.2)\]

According to the Figure 5-1, u (input torque) is represented as

\[ u = \dot{y} + \left[ e \cdot \left( \frac{K_p \cdot 10}{4096} \right) + \dot{e} \right] \cdot \left( \frac{K_d \cdot 10}{8,388,608} \right) + \left( \frac{K_i \cdot 10}{8,388,608} \right) \cdot \left[ e \cdot \left( \frac{K_p \cdot 10}{4096} \right) + \dot{e} \right] dt \quad (5.3)\]

Equation (5.2) is written in the form of two first-order differential equations as

\[ \begin{aligned}
\dot{x}_1 &= x_2 = \dot{y} \\
\dot{x}_2 &= \ddot{y} = -1.8944\dot{y} - 0.8950y + u
\end{aligned} \quad (5.4)\]

or

\[ \begin{aligned}
\dot{x}_1 &= x_2 \\
\dot{x}_2 &= -0.8950x_1 - 1.8944x_2 + u
\end{aligned} \]

With these two first-order differential equations, the system response is obtained from the C program simulation by numerical integration. Figure 5-2 shows one of the simulated results for the set of gains of \( K_p = 10, K_i = 28,000, \) and \( K_D = 40,000. \) In this simulation, parabolic function input is used as the desired path instead of the step input. The reason is that the ramp input does not create large errors initially as in the case of
step input. As a result, this eliminates undesired system response due to system shocks introduced by a large difference between the actual and desired inputs. This process provides a realistic situation where the smoothness of the system is one of the desired characteristics of the FRMC performance. As can be seen in Figure 5-2, the model follows the desired path fairly well without oscillations or any deviation away from the desired behavior. Transient response as well as the steady-state response are observed to be quite acceptable.

Figure 5-2. Simulated System Response under PID Controller
5.1.2 Experiments on 1-DOF FRMC by Implementing the PID Controller

As one knows, the objective of a PID controller is to determine the values of the three gains, $K_p$, $K_i$, and $K_d$, so that the performance of the system meets the design requirements. Here, the subscript P stands for “proportional,” I for “integral,” and D for “derivative” to indicate various gains used in the feedback loops. In this section, different gains are tested experimentally to obtain the best possible system response. Although the simulations of the PID controller have been performed earlier, the real-life situations often give different results because of the unmodeled dynamics in the simplified system model.

Figures 5-3, 5-4, and 5-5 show some of the system responses of the gains in Table 5-1 versus system position command where the plots on the left side provide the entire view of system response and the plots on the right focus on the steady-state portion. Figure 5-6 compares the system response errors in these experiments.

| Table 5-1. Gains Used in Experiments on the Actual System |
|-------------------|------------|------------|
|                  | $K_p$     | $K_i$      | $K_d$     |
| PID1              | 10        | 28,000     | 40,000    |
| PID2              | 2         | 20,000     | 40,000    |
| PID3              | 4         | 20,000     | 40,000    |
| PID4              | 2         | 10,000     | 10,000    |
| PID5              | 12        | 10,000     | 10,000    |
| PID6              | 8         | 30,000     | 20,000    |
Figure 5-3. Position Command and System Response of PID1 Gains

Figure 5-4. Position Command and System Response of PID3 Gains

Figure 5-5. Position Command and System Response of PID6 Gains
As expected, the experimental results are somewhat slightly different from the simulated results. The actual system response shows oscillations and steady-state error while the model does not. This can be explained by the fact that the model does not include the nonlinear terms such as friction in the system. Also, the model perhaps does not include the so-called "unmodeled dynamics," which is characterized by low-magnitude and high-frequency motion. The overshoot and subsequent oscillations shown in the actual system are caused from the excessive and retarding torque developed by the motor as the PID controller tries to compensate for the friction. Other factors such as Coulomb friction, dead zone, and quantization error also contribute to these errors. These factors are discussed in detail later in the chapter.

Among the three system responses shown in Figures 5-3, 5-4, and 5-5, PID1 (Fig. 5-3) which consists of $K_P = 10$, $K_I = 28,000$, and $K_D = 40,000$ show the best system response. One may argue that PID3 (Fig. 5-4) has a faster settling time than PID1, but
notice that the steady-state error of PID3 does not go to zero as shown in Figure 5-6. On the other hand, for PID 6 (Fig. 5-5) which shows that the steady-state error eventually becomes zero, the system has a longer settling time than PID1.

5.2 Development of Fuzzy Logic Controller

Fuzzy logic was first introduced by Lotfi Zadeh of the University of California at Berkeley in 1965. Since then, fuzzy logic has become one of the most successful control system schemes. Fuzzy logic provides a bridge in control system design between mathematical approaches (e.g. linear control design) and logic-based approaches (e.g. expert systems). While other approaches require an accurate model to represent the real system, fuzzy design can accommodate the ambiguities of real-world human language and logic. It provides both an intuitive method for describing systems in human terms and automation for the conversion of those system specifications into effective models.

Simplicity, flexibility, and cost effectiveness are among the other benefits of fuzzy logic. Fuzzy logic is capable of handling problems with imprecise data, and it can model nonlinear functions of arbitrary complexity. Not only do the rule-based approach and flexible membership function scheme make fuzzy systems straightforward to create, but they also simplify the design of systems and ensure that the system designer can easily update and maintain the system over time.

The fuzzy controller consists of a set of user-supplied rules of which the inputs and outputs are both fuzzy values. All control rules are used in parallel, and the recommended actions are combined according to the fuzzy control rules, which are weighted by the degree of satisfaction of the antecedent. This implies that the fuzzy controller has the
ability to control system in an uncertain or unknown environment. However, one of the fundamental problems of fuzzy control is how to establish the control rules without human expertise and knowledge of the plant [Fukumi et. al., 1996].

A user-supplied rule consists of IF-THEN statements which provide the output of a system. The rule mechanism is generally of the form:

\[ R^{(1)}: \text{IF } x_1 \text{ is } F_1^j \text{ and } x_2 \text{ is } F_2^j \text{ and } \ldots \text{ and } x_n \text{ is } F_n^j, \text{ THEN } y^j = c^j \]

\[ R^{(k)}: \text{IF } x_1 \text{ is } F_1^k \text{ and } x_2 \text{ is } F_2^k \text{ and } \ldots \text{ and } x_n \text{ is } F_n^k, \text{ THEN } y^k = c^k \]

\[ R^{(m)}: \text{IF } x_1 \text{ is } F_1^m \text{ and } x_2 \text{ is } F_2^m \text{ and } \ldots \text{ and } x_n \text{ is } F_n^k, \text{ THEN } y^m = c^m \]

where \( R^{(k)} \) means the \( k^{th} \) rule

- \( x_i \) is a real-valued input variable
- \( F_i^k \) is a fuzzy set specified by membership functions
- \( \mu_f(x_i) \) is a membership function (often defined as triangular functions)
- \( n \) specifies the number of input variables
- \( c^k \) is a real-valued constant
- \( y^k \) is the system output for this rule.

If there are \( m \) rules defined in the rule base, the system output is
\[ y = \Lambda \frac{\sum_{k=1}^{m} w^k \cdot c^k}{\sum_{k=1}^{m} w^k} \]  

(5.1)

where \( w^k \) represents a variable weight assigned to the corresponding constant \( c \)

\( \Lambda \) is defined as a scaling and tuning term.

The individual weights are computed as

\[ w^k = \prod_{i=1}^{n} \mu_{E_i^k}(x_i) \]  

(5.2)

To apply fuzzy logic to a robotics control system, the position and velocity feedback are used to compare the desired values given by the operator. The resulting errors are then used to compute the input torque of the actuator. This input torque can be considered as the torque to compensate for these errors. Therefore, the IF-THEN rules are written in the form:

\[ \text{IF } e_1 \text{ is } E_j \text{ and } ce_1 \text{ is } CE_i, \text{ THEN } y = C_{ij} \]  

(5.3)

where \( e_1 \) is defined as position error

\( ce_1 \) is defined as velocity error

\( E_j \) is the linguistic measure of the fuzzy sets of position error

\( CE_i \) is the linguistic measure of the fuzzy sets of velocity error

\( C_{ij} \) is a constant representing the torque to be applied found on a look-up table

The membership functions provide the continuity of control inputs rather than the on/off Boolean logic strategy. The weights of Equation (5.2) are now computed as:
\[ w_{ij} = \mu_{E_j}(e) \cdot \mu_{\dot{E}_i}(\dot{e}) \cdot C_{ij} \]  

(5.4)

since \( n = 2 \) (position and velocity errors). Substituting these weights into Equation (5.1),

\[
\mathbf{u} = \Lambda \frac{\sum_{i=1}^{q} \sum_{j=1}^{v} \mu_{E_j}(e) \cdot \mu_{\dot{E}_i}(\dot{e}) \cdot C_{ij}}{\sum_{i=1}^{q} \sum_{j=1}^{v} \mu_{E_j}(e) \cdot \mu_{\dot{E}_i}(\dot{e})}
\]

(5.5)

where \( q \) and \( v \) define the size of the look-up table.

5.2.1 Fuzzy Logic Controller Simulation

The fuzzy logic control scheme developed for the 1-DOF FRMC prototype uses the triangular membership functions as shown in Figure 5-7 (Position error) and Figure 5-8 (Velocity error).
Figure 5-7. Position Error Membership Functions

Figure 5-8. Velocity Error Membership Functions
The membership functions vary from 0 to 1 and can be calculated from Figures 5-7 and 5-8 with knowledge of the position error and velocity error. The control input (Equation 5.5) can then be determined utilizing the membership functions and the look-up table of constant input values (Table 5-3) with \( q = 9 \) and \( v = 9 \). The model obtained in the previous section is used to simulate the 1-DOF FRMC prototype. Moreover, the constant values in Table 5-3 represent the values of input voltage that can be provided by the actual actuator of the 1-DOF FRMC. A look-up table has to be generated that, in essence, is a set of gains for the system. According to Cha [Cha et. el., 1996], the performance of a teleoperation system is greatly influenced by the force-reflection gain. If the gain is too small, the performance is poor. If the gain is too large, the system is unstable. To simplify this process, the look-up table is set up as a function of a single base value. The base value is multiplied by the weighting corresponding to the position in the table.

In the simulations and actual experiments of the 1-DOF FRMC system, the gain matrix for scaling and tuning is set to 1.

b – base value
The look-up table coefficients as illustrated in Table 5-3 are chosen with the aim of sending the position and velocity errors to their respective zero value as shown in Figures 5-7 and 5-8 [Erbatur et al., 1995]. The location where both the position and velocity have a large negative error receives a large negative torque and vice-versa for the positive end. For the case where there is large positive position error and large negative velocity error, the corresponding table location receives a small input torque due to the correctness of the situation being somewhere in between the two error values. The same applies for the case of large positive velocity error and large negative position error. The values in between these cases are chosen in the same manner so as to produce a continuous table flow towards zero.

Figure 5-9 depicts one of the simulated results using a fuzzy logic controller where the base value is 0.5. Again, the parabolic function input is used here as the desired path for the reason stated earlier.

![Figure 5-9. Simulated System Response under Fuzzy Logic Controller](image-url)
Observed from the above figure that the model under fuzzy logic controller follows the desired path exactly. However, this may not be the case for the actual system as demonstrated in the next section.

5.2.2 Experiments on the 1-DOF FRMC by Implementing the Fuzzy Logic Controller

The fuzzy logic control method developed in the previous section is implemented on the 1-DOF FRMC prototype. All of the parameters used in the simulation are applied to the actual system. One of the main objectives of the experiments is to compare the numerical results obtained from the mathematical model and that of laboratory data. In doing so, the 0.5 base value is used in the experiments. Figure 5-10 shows the response obtained from the actual system with $b = 0.5$.

![Graph showing actual system response under fuzzy logic controller with base value of 0.5.](image)

Figure 5-10. Actual System Response under Fuzzy Logic Controller of Base Value of 0.5
When the experimental data (Figure 5-10) are compared with the simulation results obtained from mathematical model (Figure 5-9), it is observed that they match quite well with the exception of a slight overshoot in the transient behavior and minimal steady-state error. This is because, as explained earlier, in a real system there are friction and other nonlinear system characteristics, such as dead zone and quantization errors which are not considered in the simulation. These errors in a control system are almost unavoidable. The next section discusses these errors in detail.

Figures 5-11 and 5-12 show the actual system response of the 1-DOF FRMC test-bed under fuzzy logic controller with various base values.

![Figure 5-11. Actual System Response with Base Values between 0.35 to 0.5](image-url)
As can be seen from the above figures, different base values produce different system response. Thus, the fuzzy logic controller, as is the case with most controllers, the selection of the system gain is one of the most important factors that determine the performance of the system. In the case of the 1-DOF FRMC, the most appropriate base value is 0.5 for the look-up table represented in Table 5-3. Note that the results obtained above were in the case that the operator held the joystick with a loose grip.

A soft grip uses lower gains while a firm grip uses higher gains in order to provide a force-reflection sensation. As for the 1-DOF FRMC, the experiments show that for the stable region of the soft grip, the base value is in the range of 0.35-0.55; whereas for the firm grasp, the base value can be as much as 0.8-1.0. If the base value falls below the
above values, poor performance results, and higher base value causes the system to be unstable.

5.3 A Comparison of the System Performance of PID Controller and Fuzzy Logic Controller

A comparison of the system response between PID controller and fuzzy logic controller is shown in Figure 5-13. All of the system parameters used in this experiment are the same as before where the gains for PID controller are set as $K_p = 10$, $K_i = 28,000$, and $K_d = 40,000$, and the base value (b) for fuzzy logic controller is selected as 0.5.

![Figure 5-13. A Comparison of System Response between PID and Fuzzy Logic Controllers](image-url)
As can be seen in the Figure 5-13, both controllers follow the desired path quite well. The differences are that PID shows an overshoot and transient oscillations but has no steady-state error, whereas the fuzzy logic controller produces no oscillations, but it displays steady-state error and can not catch up with the desired path at the beginning as well as PID. Therefore, the choice of selecting a controller between the PID and fuzzy logic approaches will depend largely on the operator and the requirements of the tasks since each has its benefits and drawbacks. However, for the purpose of force-reflecting manual controller application, where a very high precision is not required due to the limitations on human perception, the performance of both controllers are judged to be acceptable.

5.4 Errors Caused by Nonlinear System Elements

According to Figure 5-6 (PID system response errors) and Figure 5-10 (Fuzzy logic system response), errors of control systems are attributed to static and dynamic friction and some nonlinear system characteristics. Static friction or stiction represents a retarding force that tends to prevent motion from beginning. The static friction force can be represented by the expression

\[ f(t) = \pm (F_s)_{v=0} \tag{5.6} \]

In Equation (5.6), \( f(t) \) is defined as a frictional force that exists only when the body is stationary but has a tendency of moving. The sign of the friction depends on the direction of motion or the initial direction of velocity.
The force-to-velocity relation of static friction is illustrated in Figure 5-14. Notice that once the motion begins, the static friction vanishes and dynamic or viscous friction takes over. For the 1-DOF FRMC, the static friction torque is measured to be around 0.27 lb-in.

![Figure 5-14. Force-to-Velocity Relation of Static Friction](image)

The errors at the transient portion and at the steady state are usually caused by nonlinear system elements. According to Kuo [Kuo, 1991], steady-state errors of control systems are attributed to some nonlinear system characteristics such as nonlinear friction or dead zone. The amplifier used in the control system often has the input-output characteristics shown in Figure 5-15. When the amplitude of the amplifier input signal falls within the dead zone, the output of the amplifier will be zero, and the control will not be able to correct the error if any exists. Dead-zone nonlinearity characteristics shown in Figure 5-15 are not limited to amplifiers. The flux-to-current relation of the magnetic field of an electric motor often exhibits a similar characteristic. Thus, as the current of the motor falls below the dead zone D, no magnetic flux, and; thus, no torque will be pro-
duced by the motor. On the other hand, when the input-signal magnitude exceeds a certain level, the amplifier may be subject to saturation characteristics as in Figure 5-15. Similarly, when the magnetic field of the motor is saturated, increasing the armature current will no longer produce additional torque.

![Graph](image)

**Figure 5-15. Typical Input-Output Characteristics of an Amplifier with Dead Zone and Saturation**

The output signals of digital components used in control systems, such as a microprocessors, can take on only discrete or quantized levels. This property is illustrated by the quantization characteristics shown in Figure 5-16. When the input to the quantizer is within +/- 0.5q, the output is zero, and the system may generate an error in the output whose magnitude is related to +/- 0.5q.
The Coulomb friction is also a common cause of steady-state position errors in control systems. Coulomb friction is a retarding force that has a constant amplitude with respect to the change in velocity, but the sign of the frictional force changes with the reversal of the direction of velocity. The mathematical relation for the Coulomb friction is given by

\[ f(t) = F_c \left[ \frac{dy(t)}{dt} \right] \]

Figure 5-17 shows a restoring-torque-versus-position curve of a control system. The torque curve typically can be generated by a step motor or a switched-reluctance motor, or from a closed-loop system with a position encoder. The point 0 designates a
stable equilibrium point on the torque curve, as well as the other periodic points along the axis where the slope on the torque curve is negative. The torque on either side of the point 0 represents a restoring torque that tends to return the output to the equilibrium point when some angular-displacement disturbance takes place. When there is no friction, the position error should be zero, since there is always a restoring torque so long as the position is not at the stable equilibrium point. If the rotor of the motor sees a Coulomb friction torque $T_F$, then the motor torque must first overcome this frictional torque before producing any motion. Thus, as the motor torque falls below $T_F$ as the rotor position approaches the stable equilibrium point, it may stop at any position inside the shaded band shown in Figure 5-17, and the error band is bounded by +/- $\theta_e$.

![Figure 5-17. Torque-Angle Curve of a Motor or Closed-Loop System with Coulomb Friction (Adapted from Kuo, 1994)](image-url)
CHAPTER 6

DEVELOPMENT OF A TELESENSATION SYSTEM

In this chapter, the ongoing development of a telesensation system which is being developed at the Robotics and Automation Laboratory at Florida International University in Miami is presented. Such a system consists of three distinct components: Virtual Reality (VR) unit, Force-Reflecting Manual Controller (FRMC), and Graphical User Interface (GUI). An overview of VR units is given. Furthermore, an extensive survey of commercial VR units has been conducted in order to identify the most appropriate unit for the telesensation system. Later, the design of the 3-DOF FRMC is presented. This includes a review of the actuator system design alternatives and a survey of the actuator system available commercially. In addition, various design alternatives for the 3-DOF FRMC are presented. The relative merits of different options are also discussed. Finally, the development of the GUI software is presented.

6.1 Virtual Reality Unit

A Virtual Reality (VR) unit is a visual device, similar to a helmet, that enables a person to perceive and interact with a virtual environment as if it were real [Miner and
Stansfield, 1994]. In telesensation systems, the VR unit provides the view of the remote site as the operator turns or tilts his/her head which corresponds to a remote system camera. A VR system not only provides the operator with the 3-D view of the remote site, but also sound feedback, voice input and motion tracking [Christopher and Stansfield, 1994]. A standard TV monitor is not able to provide the operator with a sense of a 3-D view of the working environment. Thus, the feeling of presence and sensation is reduced which results in poor performance [Trivedi and Chen, 1993].

One of the major advantages of having a VR unit is that the actual manipulator can be removed from the training loop while the operator is being trained. This training approach can be quite beneficial because the robot cannot be damaged by any mistreatment by an operator, and the operator should feel more comfortable during the training exercise. In addition, training scenarios can be set up easily. These scenarios usually include an emergency situation procedure training. Should the actual emergency occur, the operator would be much better in handling the situation [Miner and Stansfield, 1994]. Also, the cost associated with training personnel reduces significantly since direct hardware usage is significantly reduced.

The Current State-of-the-Art VR Systems

Vision

VR systems usually include stereo vision. Two types of displays used in lower cost systems are Liquid Crystal Displays (LCD) and CRT. The CRT display areas are usually small with high light output while flat-panel LCD displays have low weight and
optional color, but with poor resolution and relatively low light output. Thus, CRTs are more preferable in display design with folded optical paths.

In terms of complexity and realism, VR units have similar objectives of visual image generation to those in aircraft simulation. However, faster scene changes are required in the VR systems as a result of user head movements. VR units must be able to provide effective visual simulation which requires computational complexity in order to eliminate hidden lines and produce effective perspective [Burdea, 1994]. In addition, computational speed must be fast enough to provide the operator with acceptable scene update rates. Currently, one of the most powerful and popular work stations is produced by Silicon Graphics.

The image generator produces an output by receiving the signal from the measurement of head movements which are measured optically, acoustically, mechanically or magnetically. One of the most popular systems is the Polhemus Spasyn system. This technique requires only small sensors to be mounted on the head and is insensitive to most interference. However, one of the biggest disadvantages of this system is that the accuracy is affected by metal, and the environments must be mapped extensively.

Audio

An audio system is one of the most important elements in VR units. Spatially distinct sounds are important attributes of a convincing virtual reality. One approach to produce a successful virtual 3-D sound is to apply a mathematical function called Head-Related Transfer Function or HRTF. The HRTF relates to an individual’s ear shape, but generalized HRTFs have been successfully created that work for most people. Research
has shown that perceptual errors can cause problems, such as sounds behind the head that are perceived as if they were in the front of the head. These types of problems cannot be solved even when generalized HRTFs are used [Vince, 1995].

One of the most efficient VR systems, built at the Armstrong Aerospace Medical Research Laboratory, is called the Visually Coupled Airborne Systems Simulator (VCASS). The system uses miniature CRTs as image resources to produce high-resolution displays. VCASS provides a binocular field of view of 120 degrees horizontal and 60 degrees vertical. It has high bandwidth video amplifiers, programmable analog circuits for pre-distorting the images and many other features. Other proficient VR units have been produced by Honeywell for use in the “Falcon Eye,” the F-16 night attack system, the Apache attack helicopter and in other various British research projects.

Extensive teleoperation research projects using the VR technology have been developed at NASA’s AMES Research Project [Stark et. al., 1987]; the JPL to control remotely deployed robots [Bejczy, 1980]; the Automation and Robotics (A&R) Division at the Johnson Space Center (JSC) for telepresence research, robotics and extravehicular activities (EVA) analysis and training [Read et. al., 1994]; the Advanced Controls Manipulation Laboratory (ACML) at Sandia National Laboratories for waste remediation technologies; the University of Tennessee at Knoxville Mobile-Manipulator Robotics Research (M2R2); and the Oak Ridge National Laboratory (ORNL) Advanced Servo Manipulator (ASM)-based Decontamination and Decommissioning (D&D) [Trivedi and Chen, 1993].
Some of the commercial VR units available on the market are briefly reviewed below. These include the Visual Immersion Module, VIM, Liquid Image MRG2.2, Virtual Research System VR4 and Personal Use Stereoscopic Haptic, PUSH, virtual reality systems.

**Visual Immersion Module (VIM)**

The Visual Immersion Module (VIM), as shown in Figure 6-1, is produced by Kaiser Electro-Optics, Inc. There are two models available: 500HRpv and 1000HRpv. The 500HRpv employs two full-color, 0.7” Active Matrix LCD (AMLCD) displays with a resolution of 180,000 pixels per LCD. The field of view (FOV) is approximately $50^\circ$ and weighs only 26 oz. The 1000HRpv provides four full-color displays instead of two and has a vertical FOV of $30^\circ$ and $100^\circ$ horizontally. Both provide built-in Sennheiser 2-channel stereo headphones [Batsomboon et. al., 1996c].

![Figure 6-1. Visual Immersion Module (VIM)](image)
Liquid Image MRG2.2

The MRG2.2 (Figure 6-2) is one of the various VR units manufactured by the Liquid Image Corporation. The unit employs a single, full-color AMLCD display type with a resolution of 240 × 720 pixels per eye. It has a FOV of 84° horizontally and 65° vertically. Internally mounted microphones and positional tracker are two of the many options that can be incorporated.

Figure 6-2. Liquid Image MRG2.2

Virtual Research Systems VR4

The VR4 (Figure 6-3) is manufactured by Virtual Research Systems, Inc. This light-weight unit (33 oz.) has a field of view of 60° diagonal at 100% overlap and 67° at 85% overlap. Each eye has a resolution of 742 × 230 pixels which is equivalent to 56,887 triads. The VR4 employs a 1.3” diagonal AMLCD display type and Sennheiser HD440 digitally compatible headphones [Batsomboon et. al., 1996c].
Personal Use Stereoscopic Haptic (PUSH)

The Personal Use Stereoscopic Haptic (PUSH), as shown in Figure 6-4, is a desktop immersive display produced by Fakespace. The unit provides an adjustable field of view of $30^\circ$ to $140^\circ$ with a resolution of $1280 \times 1024$ triads per eye. It has 6-DOF control with 3-DOF PUSH interface. A test has been conducted by Fakespace to examine the unit. Users ranging from expert to novice were asked to navigate through a virtual test environment. With PUSH technology, the company claims that the users were able to navigate in a large virtual space or zoom in to see the objects from different viewpoints.
For the purpose of implementing a VR unit in a telesensation system, although any of the systems reviewed above might be used, either the VIM 1000HRpv or VR4 would be more suitable. Both systems provide built-in stereo headphones and a good range of field of view with fine resolution. Their lightweight and reasonable costs make them more attractive.

6.2 Design of a 3-DOF Force-Reflecting Manual Controller

A force-reflecting manual controller (FRMC), or joystick, is one of the devices that can be used to control remote systems in teleoperation. A joystick is often a better control device than other available options such as a mouse, switchbox, keyboard or touch-screen input because the operator identifies better with the task [Johnsen and Corliss, 1971]. However, to apply the concept of telesensation to a conventional teleoperation system, the joystick should be able to reflect forces experienced at the remote site. Force feedback is one of the most significant elements of feedback information for a telesensation system. It is fundamental for mechanical support, sense of balance and a feel of touching real objects. It conveys information that is essential in many activities such as training, design analysis and hazardous-environment task simulations [McNeely, et. al., 1995]. The FRMC provides a virtual force [Repperger et. al., 1995] which enhances the realism of the virtual reality-based telesensation system; thus, the performance of the operator is greatly improved.

Unfortunately, most of the force-reflecting manual controllers are bulky, complex, and high cost. In order to improve the design to meet criteria such as compactness, port-
ability, and low costs, the motors currently available on the market from various companies are surveyed. The actuators to be used in constructing the 3-DOF FRMC will be based upon the data obtained. In addition, a variety of conceptual designs of the 3-DOF FRMC are proposed.

6.2.1 Actuator System Design Alternatives

Currently, two actuator system designs; (i) motor and speed reducer combination, and (ii) direct drive, have been implemented in the development of the force-reflecting manual controller.

Motor and Speed Reducer Combination System

This traditional system has been implemented in the majority, if not all, of force-reflecting manual controllers. The system consists of a servomotor and gear reduction in order to satisfy the output torque requirement. One of the advantages of this system is that the motors can be very small and use high gear ratio sets to obtain the desired output torque [Tosunoglu et. al., 1996b].

Table 6-1 summarizes the surveyed data of the brushless DC servomotors which will be matched with the suitable gearhead so that the system provides the desired torque.

Note 1: Sizes shown indicate motor dimensions only.
Note 2: Highlighted motor indicates the most suitable selection in this group.

Spur and planetary gears are the most suitable for this type of application. A high gear ratio and nearly zero backlash can be obtained from planetary gears. However, because of the tight mechanism, the contact area between the teeth is relatively large, which makes them suffer from high friction. While spur gears have relatively lower friction than planetary gears, spur gears have more backlash.

An example of a system that combines a DC brushless motor and gearhead can be obtained from the SIPCO company. The system consists of the motor model 17PL030 (the technical data is given in Table 6-1) combined with the compatible planetary gearhead model RE 34/50, with a ratio of 50:1, a length of 1.61 inches and a weight of 0.46 lb. Thus, the actuator will provide a peak torque of 425 oz-in and the system will have a
force reflection of 4.43 lb. The overall dimensions of the actuator are 5.31 inches in length, 1.34 inches in diameter and 1.34 lb. in total weight.

The most compact actuator found is from the Inland Company. The system consists of the motor model RBEH 00412 (Table 6-1) with a gearhead ratio of 45:1, a length of 1.68 inches and a weight of 0.65 lb. Hence, the actuator will provide the peak torque of 500 oz-in, and the system will be capable of reflecting forces up to 5.20 lb. The overall size of the actuator is 3.42 inches in length, 0.96 inch in diameter and a total weight of 0.93 lb.

Table 6-2 lists some of the important properties of the two systems described above.

One of the major drawbacks of this system, however, is the friction and backlash problems caused by the gearing system. Other disadvantages include poor dynamic response and difficulty in controlling torque and fine movement.

**Direct Drive System**

A direct drive system couples the system’s load directly to the motor without the need of intermediate transmission elements such as gears or belts. Such a system is brushless and gearless; it eliminates friction and backlash problems. As a result, better accuracy and smooth rotation can be obtained. The reliability of the system is also improved because a smaller number of components is used.

However, the motors need to have an efficient cooling system since the motor must carry the entire load directly and continuously; otherwise the motor may be overheated and burned out. Thus, the actuators must be carefully selected.

The following table (Table 6-3) presents some of the sample surveyed data obtained from different manufacturers regarding rare-earth permanent magnet brushless DC motors. The motors represented in the table below have the range of required torque with reasonable sizes for the 3-DOF FRMC design.

Of these various manufacturers, Inland is judged to be the most suitable company for the development of a 1-DOF FRMC prototype. It provides high-performance motors with relatively smaller sizes than the other companies. Among the Inland actuators, three models in Table 6-3 provide the range of our desired torque with the most compact sizes.

Aside from the output torque, the size of these motors is of great importance in this project. The configuration of model 01516 is similar to those of conventional motors where the length is longer than the diameter while the models 01812 and 02111 are of the pancake type, where the diameters are larger than the lengths. The influence of these different configurations will have great effects on the design of the 3-DOF FRMC.
Proposed Actuator System Design for the 3-DOF Force-Reflecting Manual Controller

As can be seen from the above review of two alternative designs, the direct drive system can be as compact as the traditional system with motor and gearhead. Therefore, at the current state, the proposed design of the 3-DOF FRMC will be of the direct drive structure using a brushless DC motor as the actuator to drive the system. The possible motor that will be used in our development is manufactured by the Inland Company. Figure 6-5 shows the dimensions of the selected model.
Such a system will most likely satisfy the criteria of the design with advantages as follows:

- Compact size
- Light Weight
- Minimal friction
- Zero backlash
- Precise
- Responsive
- Low noise
- Reliable
- Infrequent maintenance requirements
- Clean and quiet operation
6.2.2 3-DOF FRMC Design Alternatives

A variety of design alternatives have been developed for the 3-DOF FRMC with some promising results. Most of these are in the form of parallel structure since it allows a movement in any axis without causing force and inertia components on the other two axes. The serial structure is also being considered because of its simple configuration and large workspace.

The general design criteria include:

- Compact arrangement for portability and easy operation
- Simple mechanism for inexpensive construction and reliable operation
- Minimum friction and backlash for precise operation
- Direct drive configuration for the elimination of gear sets

The removal of gear sets will cause a growth in actuator size due to the absence of speed-reducing mechanisms in the system. However, it in turn provides a simpler arrangement with a quicker response, a wider margin of reliability, and longer life since there are fewer parts in the system that are prone to loads, fatigue and breakage. The following section describes the four most promising design alternatives.
Design Alternative 1

In this design, the X- and Y-direction actuators are located in the same plane, an arrangement that reduces the height of the controller but also uses extra space in the horizontal dimensions.

The design of the vertical shaft assembly (piece 1) provides a slim connection with both horizontal shafts (pieces 2 and 3) (See Proposed Design 1 in Appendix for definition of various pieces). This offers an excellent reduction in friction, although it may be prone to backlash. The vertical shaft assembly does not allow the positioning of the Z-direction actuator to be inside the mechanism. Instead, the Z-direction actuator is
best placed within the handle grip itself for compactness. However, in order to be able to place the actuator inside the handle, the actuator must be sufficiently small. As a result, the force-reflection capability is reduced.

The shape of the X-direction shaft (piece 2) poses some challenges and may cause extra expenses during manufacturing. The X-direction shaft has a complex form with solid circular rod-shaped ends merged with a slotted center for passage of the vertical shaft assembly. A detailed illustration of the alternative designs is provided in the Appendix.

**Design Alternative 2**

![Figure 6-7. Proposed Design 2 (Parallel Configuration)](image-url)
Figure 6-7 shows the second proposed design for the 3-DOF force-reflecting manual controller. This design utilizes a sphere as a guide to the movement of the mechanism.

The handle shaft (piece 1) is directly connected to the sphere to provide the movement for the X- and Y-direction shafts in all directions. The sphere also houses the Z-direction servomotor. The size of this actuator determines the minimum dimensions of the sphere.

The sphere reduces the number of different parts of the mechanism but increments its friction due to the large contact area. The use of teflon in the grooves will reduce the friction. The multiple tasks of the sphere dictate an inherently intricate design. Because of this, the manufacturing and assembly of the sphere will increase the cost of the unit.

The sphere creates other problems in servicing the system since it shields the third actuator, and the whole controller has to be completely disassembled to reach this servomotor. Another concern is how the location of the wiring connecting this actuator with the rest of the system will be achieved.
Figure 6-8 demonstrates the third proposed design, a gimbal type assembly. The arrangement offers one of the best alternatives for the controller. The gimbal arcs occupy less space than a sphere and they are much simpler to design and manufacture. They provide adequate space to locate the Z-direction servomotor and yet offer excellent accessibility without having to disassemble the entire system.

The design of the universal connection (piece 1 in Appendix) is critical for the proper operation of the entire controller; it is the most complex part of the design. This
part allows the displacement of the gimbals in all directions, operating precisely with minimum friction and backlash. Both the handle and the frame of the Z-direction actuator are attached to it at each end, demanding a sturdy construction. The connecting shaft between them must pass through piece 1 with enough play to provide precise operation but also with enough tightness to avoid any unnecessary play. All these conditions need to be considered carefully in the structural design of the controller.

**Design Alternative 4**

![Figure 6-9. Proposed Design 4 (Serial Configuration)]
Figure 6-9 depicts the design alternative in serial structure. This design provides the largest workspace among the above designs. This simple configuration makes it easy to manufacture, assemble and disassemble.

However, this serial structure has a major advantage inherent to serial systems. The actuator that rotates about the X axis must carry the weight of the two actuators that rotate about the Y and Z axes, and likewise, the actuator that rotates about the Y axis must carry the weight of the actuator that rotates in the Z direction. As a result, the actuators will have to be selected such that they are capable of carrying the load of the other and at the same time to provide the required force reflection. This, in turn, influences the size of the actuator and the oversize of the entire system.

With the above consideration, the serial configuration may not be as compact as expected. In addition, the stiffness and precision of the system become questionable because of this arrangement.

Comparison of Design Alternatives

Table 6-5 provides a comparative summary of the principal design parameters considered and how each alternative meets these parameters.

The four design alternatives offer room for improvement, especially in the location of the actuators and general dimensions, which are largely determined by the commercially available motors. Alternatives 2 and 3 offer greater flexibility in the servomotor location, which is impaired by alternative 1 where the location of actuators cannot be easily changed.

Alternative 3 offers a better arrangement for actuator location than alternative 2, and the latter offers an advantage by using simpler parts. Despite the advantages of the parallel structure, alternative 4 with a serial structure can be an attractive design alternative because of its simple arrangement.
6.3 Development of Graphical User Interface (GUI)

Computer-based simulations and training are very important tools in critical operations where the task needs to be operated without an error. Otherwise, the operator does not have the opportunity to practice and gain expertise in the operation. Creating a realistic simulation assists the operator to learn the process before the actual operation occurs. Thus, the performance of the operator is greatly improved when operating on the actual task. For advanced operations such as hazardous material handling in nuclear reactors and space missions, real-time graphical simulation is considered to be one of the most important tools for an advanced teleoperator system [De Rossi et. al., 1997].

The goal of the development of an advanced graphical user interface software for a teleoperation system is to provide the operator with various options of operating modes such that the tasks can be achieved with relative ease and fidelity. However, the package should be easy to use and relatively simple to implement for any remote system.

The software package demonstrates that it is capable of accepting multiple inputs from different devices. In this case, it provides connections to video cameras, CCD cameras, force-reflecting manual controller, and virtual reality unit. Unlike many other software packages developed on mainframe workstations, our GUI software operates on a standard PC computer. This allows us to reduce the costs and simplify the entire process considerably.

The graphical user interface is being developed in a C++ environment. Several versions of the interface software have been developed. One of the earlier versions, shown in Figure 6-10, was developed in the Windows environment. This version seemed
to be more user-friendly since it facilitated the manipulation of different windows. However, programming in a Windows platform requires much more space and memory than on a DOS platform [Ezzell, 1990].

Figure 6-10. Windows-Based Version of the Interface Software

Figure 6-11 shows the most recent of the interface software, which is being developed on a DOS platform. The software is written using the concept of object-oriented programming: the same concept applied to the Windows environment [Ezzell, 1990]. One of the advantages of working on the DOS platform is that the program is developed in
terms of modularity. This allows the system designer to easily add or remove any features from the package. Thus, the software can be used for any remote system.

Figure 6-11. DOS-Based Version of the Interface Software

As illustrated in Figure 6-11, the system parameters for the telesensation system include position scaling, force scaling, force/torque sensor sensitivity, and robot workspace. Other features include rereferencing, control mode (position or velocity), control scheme (open or closed loop), and Degree of Freedom (DOF) setting (joint mode, Cartesian mode, orientation mode). In addition, a number of different windows (video, simulation, VR) of graphical presentation can be viewed simultaneously to enhance the percep-
tion of the operator. At the bottom of the screen, the status bar provides the information of all the system parameters and other settings. In the event that the program detects a problem, it alerts the operator with a message status bar.

The flowchart diagram of a recent version of the interface software is shown in Figure 6-12. The software continuously receives signals from different devices, interprets the data, and processes the data depending on the source of the signals. The input data is received from various sources:

- Mouse and keyboard: The mouse and keyboard provide system parameters set by the user.
- Encoder: The encoder provides the manual controller position as the user controls the robot with the force-reflecting manual controller.
- Force/Torque (FT) sensor: The force feedback is provided by the FT sensor in the event that the robot experiences external forces.
- Head Mounted Display (HMD): The HMD tracks the movement of the user's head and provides 3-D visual effects.
The system parameters can be changed at any instant even during the operation since the program routinely updates the variables. After the changes are made, the program stores and saves the new variables within its own database. This software is written in the simplest manner so that real-time operation is achieved.
In chapter 3, the fundamental components of force-reflecting teleoperation systems are reviewed. These are actuators, transmission systems, sensors, computer hardware, computer interface, and computer software.

In chapter 4, a 1-DOF FRMC prototype is designed and developed to demonstrate the principle of the force-reflecting manual controller. The specifications of the system components are outlined. These include a brushless DC motor, encoder, amplifier, interface board, force/torque sensor, and PUMA 760 industrial robot. The system parameters are then identified for the purpose of constructing a mathematical model. The least squares method is used to obtain the model in the form of an ARX model. A variety of different order systems are obtained to compare the system response with the actual response. The results show that the 2nd- and 3rd-order system models are capable of producing the output fairly well. However, for simplicity, the 2nd-order model is selected to represent the 1-DOF FRMC prototype system dynamics.

The model validation is performed by creating the block diagram of the servo loop U500 controller and simulating its performance numerically. The results are compared with the actual system response for different sets of gains. Although the model yields the output slightly different from the actual response, it displays a very similar behavior of the actual response. Considering this criterion, the model is judged to be valid.

In chapter 5, two control methods, PID and fuzzy logic controllers, are numerically simulated, using the model obtained from the previous chapter, and experimentally tested on the 1-DOF FRMC prototype. A comparison of the system response between the output produced by the model and the actual system for both types of controllers is conducted. The results show that the actual system displays oscillations and steady-state er-
ror while the model does not. This is true for both PID and fuzzy logic controllers. It is concluded that these errors are caused by nonlinearities and high-frequency dynamics terms that are not included in the model. Unmodeled dynamics are characterized by low-magnitude and high-frequency motion, and nonlinear terms include Coulomb friction, dead zone and quantization errors.

Furthermore, the range of the system gains for the fuzzy logic control method is established for two types of grasp motion: loose grasp and firm grasp. In order for the system to stay in the stable region, low gains are used for the soft grip whereas higher gains are required for the firm grip to provide a stronger sensation force reflection. From the experimental results, the base value of 0.35-0.5 is to be used for the soft grasp, and 0.8-1.0 for firm grasp. (The base value was defined in Chapter 5, Section 5.2.)

In addition, the performance of PID and fuzzy logic controllers on the 1-DOF FRMC is compared. The results show that each has its benefits and drawbacks. For instance, PID produces transient oscillations but no steady-state error while the fuzzy logic controller shows slower response and displays some steady-state error, but no oscillations. Note that these errors are minimal such that human cannot detect, and as a result, both controllers are considered to be acceptable for the purpose of force-reflecting manual controller application.

In chapter 6, the concept of the telesensation system is presented. The main components of the system, which includes the Virtual Reality unit, Force-Reflecting Manual Controller, and Graphical User Interface, are discussed. Commercial VR units are presented in order to identify a suitable unit for the ongoing development of the telesensation system. After a thorough study on these units, either Kaiser Electro-Optics’s VIM
1000HRpv or Virtual Research Systems's VR4 can be implemented in the system. Both systems provide built-in stereo headphones and a good range of field of view with fine resolution. Their lightweight and reasonable costs make them more attractive. In the section on force-reflecting manual controllers, the results of a survey on the electric motors currently available in the market is presented, and the four design alternatives are proposed. At this stage, it is concluded that the parallel configuration (design alternative 3 with gimbal configuration) with direct-drive actuator system is the most compact and promising design because it provides a good range of workspace and ease of assembly. Finally, the graphical interface software is developed in the C++ environment. Both Windows-based and DOS-based versions are developed. However, the final decision is made to fully develop the software on a DOS-based platform because it is relatively faster when real-time operation is one of the measurements. The software is used to interface with various components such as CCD camera, encoder, force/torque sensor and VR unit in the future.

7.2 Recommendations

Although the goal of this work has been achieved, looking back at the work conducted, we can always identify areas where further improvement can be introduced. In this work, a better controller card may have been selected for the 1-DOF testbed.

The compatibility of the C library of the controller card is limited to an older version of the C++ compiler (Borland C++ version 4.0) than is available currently. This restriction made it impossible to develop the GUI software in the newer version of the C++
compiler. As a result, the GUI software was taken longer time to develop since the older version of the C++ compiler is not user-friendly as the latest version.

7.3 Future Work

As for the future work, the concept of the telesensation system will be fully implemented. This includes the development of a 3-DOF FRMC, the addition of the VR unit, and the complete version of the GUI software package. Each of these components will involve the work described below.

(i) The development of a 3-DOF FRMC

A 3-DOF FRMC will be developed based on the design alternatives from this work. The main concern in developing this system is the size of the actuator. This is the most crucial factor because the size of the system will be determined mainly from the size of the actuator. Therefore, an extensive survey of actuators must be conducted in order to identify the most compact system available in the market. In addition, a direct-drive configuration is considered to be the most promising candidate since the actuators today are small, powerful, and they are capable of carrying loads without the need of the transmission elements such as gears. This, in turn, will dramatically reduce backlash and friction.

(ii) The implementation of a VR unit

A VR unit will be implemented as an additional visual feedback beside the CCD camera that is attached on the remote system. This unit will greatly improve the visual perception of the operator since it is generally easier to identify 3-D objects than two-dimensional objects. A survey of the commercial units has been conducted in this work,
but a more detailed study must be performed, especially on the software package. The software program must provide built-in features to create new environments with ease. For instance, a description of the remote environment (such as the nuclear reactors) must be developed with relative ease. In addition, the software needs to be compatible with the FRMC and GUI software.

(iii) The development of a complete GUI software

A GUI software package will be fully developed for the use of the 3-DOF FRMC. Various components such as VR unit, microphone, speakers, etc. must be integrated into this software with relative ease. The software should also be developed to the point where it can control and manipulate a 6-DOF or even redundant (robots with more than 6 degrees of freedom) remote system. This may be possible by developing a toggle button where the operator can control a group of joints at a time and switch the control mode between translational and rotational motions. Alternatively, two 3-DOF joysticks may also be developed for this purpose.

After the development of above components, a full-scale prototype can be built and its operation improved as a testing program is carried out and modifications in mechanical design, controller and software are implemented. Once the laboratory evaluations and system modifications are completed, the system can be tested in the field in a suitable application.

APPENDIX

CONCEPTUAL DESIGN OF 3-DEGREE-OF-FREEDOM
FORCE-REFLECTING MANUAL CONTROLLER

- Proposed Design 1
- Proposed Design 2
- Proposed Design 3
- Proposed Design 4
ACTUATOR #3 INSIDE HANDLE

ROTATION OF HANDLE PROVIDES INPUT TO ACTUATOR INSIDE

ACTUATOR #1

FOR ROTATION IN Y PIECE #1 ROTATES PIECE #3 USING CENTER OF PIECE #1 AS A PIVOT

PIECE #3

TIGHTNESS OF FITTING DETERMINES THE FRICTION OR BACKLASH OF THE ARRANGEMENT

FOR ROTATION IN X PIECE #1 SLIDES THROUGH PIECE #3 CAUSING PIECE #2 TO ROTATE

PROPOSED DESIGN 1
Rotation of handle is transmitted to actuator #3 via piece #1.

Shape of piece #1 enables direct linkage of handle and actuator #3.

Fitting of sphere and pieces determines the friction or backlash of entire arrangement.

For rotation in Y, piece #1 rotates sphere, and the latter rotates piece #2, and slides through piece #3.

Piece #2 & piece #3 are similar.

Proposed Design 2.
HANDLE FOR ROTATION IN SHAFT FOR ROTATION IN Z
HANDLE ROTATES PIECE #3 ROTATING PIECE #2 AND INPUTING MOTION IN ACTUATOR #1

THE FITTING OF PIECE #1 WITH PIECE #2 & #3 IS RESPONSIBLE FOR THE FRICTION OR BACKLASH OF ENTIRE ARRANGEMENT

FOR ROTATION IN Y HANDLE ROTATES PIECE #1 THROUGH GROOVE OF PIECE #2 ROTATING PIECE #3 AND INPUTING MOTION IN ACTUATOR #2

FOR ROTATION IN Z A ROTATION IN HANDLE CAUSES SHAFT TO TRANSMIT ROTATION TO ACTUATOR #3

PIECE #1

PIECE #2

PIECE #3

ACTUATOR #3 (FRAME FIXED TO PIECE #1)

PROPOSED DESIGN 3
FOR ROTATION IN X, MOVEMENT OF HANDLE IS TRANSMITTED TO ACTUATOR #1, BRACKET #1, AND BRACKET #2, PROVIDES INPUT TO ACTUATOR #3

FOR ROTATION IN Z, THE ROTATION OF THE HANDLE PROVIDES INPUT TO ACTUATOR #1

FOR ROTATION IN Y, MOVEMENT OF THE HANDLE IS TRANSMITTED TO ACTUATOR #1 AND BRACKET #1, PROVIDING THE INPUT TO ACTUATOR #2

PROPOSED DESIGN 4
